**Table 9-31. DMA4\_GCR**

<b>Address Offset</b>	0x0000 0078	<b>Instance</b>	SDMA
<b>Physical Address</b>	0x4805 6078		
<b>Description</b>	FIFO sharing between high and low priority channel. The Maximum per channel FIFO depth is bounded by the low and high channel FIFO budget. The high respectively low priority channels maximum burst size must be less than the min (high respectively low priority channel FIFO budget , per channel maximum FIFO depth)		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								ARBITRATION_RATE								HI_LO_FIFO_BUDGET		HI_THREAD_RESERVED		RESERVED				MAX_CHANNEL_FIFO_DEPTH							

Bits	Field Name	Description	Type	Reset
31:24	RESERVED	Reserved. Write 0s for future compatibility. Read returns 0.	RW	0x00
23:16	ARBITRATION_RATE	Arbitration switching rate between prioritized and regular channel queues	RW	0x01

Bits	Field Name	Description	Type	Reset
15:14	HI_LO_FIFO_BUDGET	<p>Allow to have a separate Global FIFO budget for high and low priority channels.</p> <p>For Hi priority Channel: (Per_channel_Maximum FIFO depth + 1) x Number of active High priority Channel =&lt; High Budget FIFO</p> <p>For Low priority channel: (Per_channel_Maximum FIFO depth + 1) x Number of active Low priority Channel =&lt; Low Budget FIFO</p> <p>0x0: no fixed budget for neither higher nor lower priority channel</p> <p>0x1: 75% of FIFO for low priority and 25% for high priority channels</p> <p>0x2: 25% of FIFO for low priority and 75% for high priority channels</p> <p>0x3: 50% of FIFO for low priority and 50% for high priority channels</p>	RW	0x0
13:12	HI_THREAD_RESERVED	<p>Allow thread reservation for high priority channel on both read and write ports.</p> <p>0x0: No ThreadID is reserved on the Read Port for high priority channels. No ThreadID is reserved on the Write Port for high priority channels.</p> <p>0x1: Read Port ThreadID 0 is reserved for high priority channels. Write Port ThreadID 0 is reserved for high priority channels.</p> <p>0x2: Read port ThreadID 0 and ThreadID 1 are reserved for high priority channels. Write Port ThreadID 0 is reserved for high priority channels.</p> <p>0x3: Read PortThreadID 0, ThreadID 1 and ThreadID 2 are reserved for high priority channels. Write Port ThreadID 0 is reserved for high priority channels.</p>	RW	0x0
11:8	RESERVED	Reserved. Write 0s for future compatibility. Read returns 0.	RW	0x0
7:0	MAX_CHANNEL_FIFO_DEPTH	<p>Maximum FIFO depth allocated to one logical channel. Maximum FIFO depth can not be 0x0. It should be at least 0x1 or greater. Note that If channel limit is less than destination burst size enough data will not be accumulated in the data FIFO and it will never be sent out on the WR port. The burst size should be less than the FIFO limit specified in this bit field.</p>	RW	0x10

<b>Address Offset</b>	0x0000 0080 + (* 0x60)	<b>Index</b>	i = 0 to 31
<b>Physical Address</b>	0x4805 6080 + (* 0x60)	<b>Instance</b>	SDMA
<b>Description</b>	Channel Control Register		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								WRITE_PRIORITY	BUFFERING_DISABLE	SEL_SRC_DST_SYNC	PREFETCH	SUPERVISOR	RESERVED	SYNCHRO_CONTROL_UPPER	BS	TRANSPARENT_COPY_ENABLE	CONST_FILL_ENABLE	DST_AMODE	SRC_AMODE	RESERVED	WR_ACTIVE	RD_ACTIVE	SUSPEND_SENSITIVE	ENABLE	READ_PRIORITY	FS	SYNCHRO_CONTROL				

Bits	Field Name	Description	Type	Reset
31:27	RESERVED	Reserved. Write 0s for future compatibility. Read returns 0.	RW	0x00
26	WRITE_PRIORITY	Channel priority on the Write side 0x0: Channel has low priority on the Write side during the arbitration process 0x1: Channel has high priority on Write sided during the arbitration process	RW	0x0
25	BUFFERING_DISABLE	This bit allows to disable the default buffering functionality when transfer is source synchronized. 0x0: buffering is enable across element/packet when source is synchronized to element, packet, frame or blocks 0x1: buffering is disabled across element/packet when source is synchronized to element, packet, frame or blocks	RW	0x-
24	SEL_SRC_DST_SYNC	Specifies that element, packet, frame or block transfer (depending on CCR.bs and CCR.fs) is triggered by the source or the destination on the DMA request 0x0: Transfer is triggered by the destination. If synch on packet the packet element number is specified in the CDFI register 0x1: Transfer is triggered by the source. If synchronized on packet the packet element number is specified in the CSFI register	RW	0x-
23	PREFETCH	Enables the prefetch mode 0x0: Prefetch mode is disabled. When Sel_Src_Dst_Sync=1 transfers are buffered and pipelined between DMA requests 0x1: Prefetch mode is enabled. Prefetch mode is active only when destination is synchronized. It is SW user responsibility not to have at the same time Prefetch=1 when Sel_Src_Dst_Sync=1. This mode is not supported	RW	0x0
22	SUPERVISOR	Enables the supervisor mode 0x0: Supervisor mode is disabled 0x1: Supervisor mode is enabled	RW	0x0
21	RESERVED	Reserved for non-GP devices	RW	0x0
20:19	SYNCHRO_CONTROL_UPPER	Channel Synchronization control upper (used in conjunction with the 5 bits of synchro channel <a href="#">DMA4_CCRi[4:0]</a> ) Used in conjunction, as two msb, with the five bits of the synchro channel bit field.	RW	0x0
18	BS	Block synchronization This bit used with the fs to see how the DMA request is serviced in a synchronized transfer	RW	0x-

Bits	Field Name	Description	Type	Reset
17	TRANSPARENT_COPY_ENABLE	Transparent copy enable 0x0: Transparent copy mode is disabled 0x1: Transparent copy mode is enabled	RW	0x-
16	CONST_FILL_ENABLE	Constant fill enable 0x0: Constant fill mode is disabled 0x1: Constant fill mode is enabled	RW	0x0
15:14	DST_AMODE	Selects the addressing mode on the Write Port of a channel. 0x0: Constant address mode 0x1: Post-incremented address mode 0x2: Single index address mode 0x3: Double index address mode	RW	0x-
13:12	SRC_AMODE	Selects the addressing mode on the Read Port of a channel. 0x0: Constant address mode 0x1: Post-incremented address mode 0x2: Single index address mode 0x3: Double index address mode	RW	0x-
11	RESERVED	Reserved. Write 0s for future compatibility. Read returns 0.	RW	0x0
10	WR_ACTIVE	Indicates if the channel write context is active or not 0x0: Channel is not active on the write port 0x1: Channel is active on the write port	R	0x0
9	RD_ACTIVE	Indicates if the channel read context is active or not 0x0: Channel is not active on the read port 0x1: Channel is currently active on the read port	R	0x0
8	SUSPEND_SENSITIVE	Logical channel suspend enable bit 0x0: The channel ignores the MSuspend even if EMUFree is set to 0. 0x1: If EMUFree is set to 0 and MSuspend comes in then all current OCP services (single transaction or burst transaction as specified in the corresponding CSDP register) have to be completed before stopping processing any more transactions	RW	0x0
7	ENABLE	Logical channel enable. It is SW responsibility to clear the CSR register and the IRQSTATUS bit for the different interrupt lines before enabling the channel. 0x0: The logical channel is disabled 0x1: The logical channel is enabled	RW	0x0
6	READ_PRIORITY	Channel priority on the read side 0x0: Channel has low priority on the Read side during the arbitration process 0x1: Channel has high priority on read sided during the arbitration process	RW	0x0
5	FS	Frame synchronization This bit used with the BS to see how the DMA request is serviced in a synchronized transfer FS=0 and BS=0: An element is transferred once a DMA request is made. FS=0 and BS=1: An entire block is transferred once a DMA request is made. FS=1 and BS=0: An entire frame is transferred once a DMA request is made. FS=1 and BS=1: A packet is transferred once a DMA request is made. All these different transfers can be interleaved on the port with other DMA requests.	RW	0x-

Bits	Field Name	Description	Type	Reset
4:0	SYNCHRO_CONTROL	Channel synchronization control This bit field used with the second_level_synchro_control_upper (as two msb) 0000000 : Is reserved for non synchronized LCH transfer xxxxxxx (from 1 to 127) There are 127 possible DMA request to assign to any LCH. <b>Note:</b> The channel synchronization control registers are 1-based. For example, to enable the S_DMA_1 request, SYNCHRO_CONTROL bits (formed by DMA_CCRi[20:19] and DMA4_CCRi[4:0]) must be set to 0x2 (DMA request number + 1).	RW	0x0

## Interrupt Controller

---

---

---

This chapter gives an overview of the interrupt controllers (INTCs) and describes in detail the MPU subsystem interrupt controller (MPU\_INTC) module.

---

**NOTE:** Some features may not be available or supported in your particular device. For more information, see Chapter 1, the Device Family section, and your device-specific data manual.

---

Topic	Page
<b>10.1 Interrupt Controller Overview .....</b>	<b>1047</b>
<b>10.2 Interrupt Controller Environment .....</b>	<b>1049</b>
<b>10.3 MPU Subsystem INTCPS Integration .....</b>	<b>1050</b>
<b>10.4 Interrupt Controller Functional Description .....</b>	<b>1055</b>
<b>10.5 Interrupt Basic Programming Model .....</b>	<b>1059</b>
<b>10.6 Interrupt Controller Register Manual .....</b>	<b>1068</b>

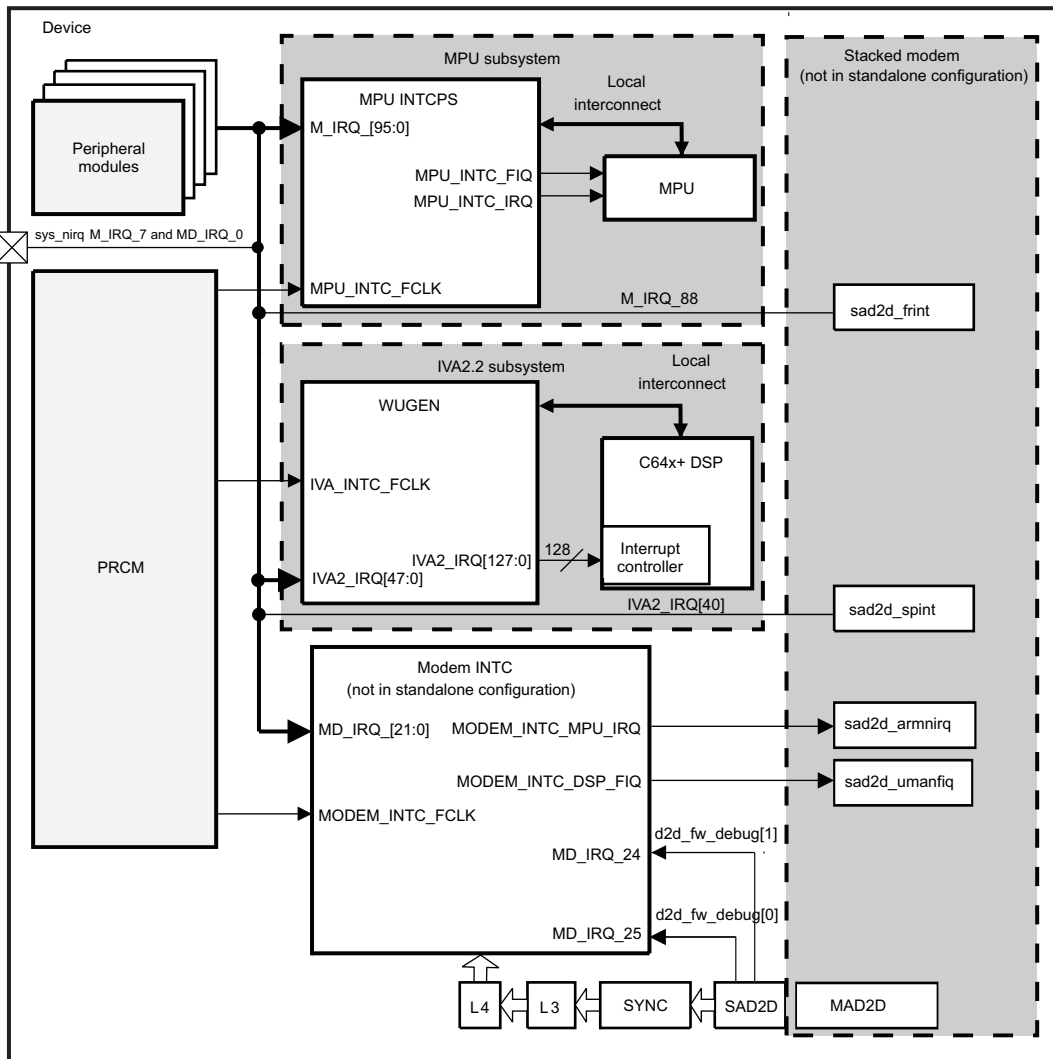

## 10.1 Interrupt Controller Overview

The device provides three interrupt controller (INTC) modules:

- **MPU subsystem INTC (INTCPS):** This module handles all MPU-related events, using Priority Threshold. It communicates with the public ARM Cortex-A8 processor using a private local interconnect, and runs at half the speed of the processor.
- **IVA2.2 subsystem INTC:** This module is a specific combination of WUGEN (wake-up generator) and the C64x+ DSP interrupt controller (IC). It is used in the device, but is not described in detail in this chapter. For detailed information about this INTC, see [Chapter 14, IVA2.2 Subsystem](#).
- **Modem INTC:** This module is an L4-mapped INTC that allows the regrouping of all the interrupts sent to the modem subsystem in stacked mode. It is seen as a level 2 INTC by the MPU and IVA2.2 subsystems. This modem INTC is integrated in the stand-alone device, but it is used only with the stacked modem. Therefore, it is not described in detail in this TRM, which focuses on the stand-alone device.

[Figure 10-1](#) shows the internal interrupt scheme with optional modem INTC (not used in the stand-alone configuration).

Figure 10-1. Interrupt Controllers Highlight

108-001

## 10.2 Interrupt Controller Environment

The INTC can handle two types of interrupts originating from an external device:

- sys\_nirq interrupt inputs:

The MPU INTC and modem INTC handle external interrupts through a dedicated sys\_nirq interrupt line that connects the two INTC modules with a power IC, respectively. An interrupt can generate a system wake-up event.

If the system is idle and the external interrupt is masked, the interrupt cannot wake up the system. Like other interrupt lines, the external interrupt is active at low level and is acknowledged by the software according to the common programming model.

---

**NOTE:** If the CORE power domain is in retention (CSWR or OSWR) or off mode, the interrupt requests (internal or external), the MPU INTC, and the modem INTC (in the CORE domain) have no effect. The CORE power domain does not wake up, and the interrupt is not signaled to the MPU/modem.

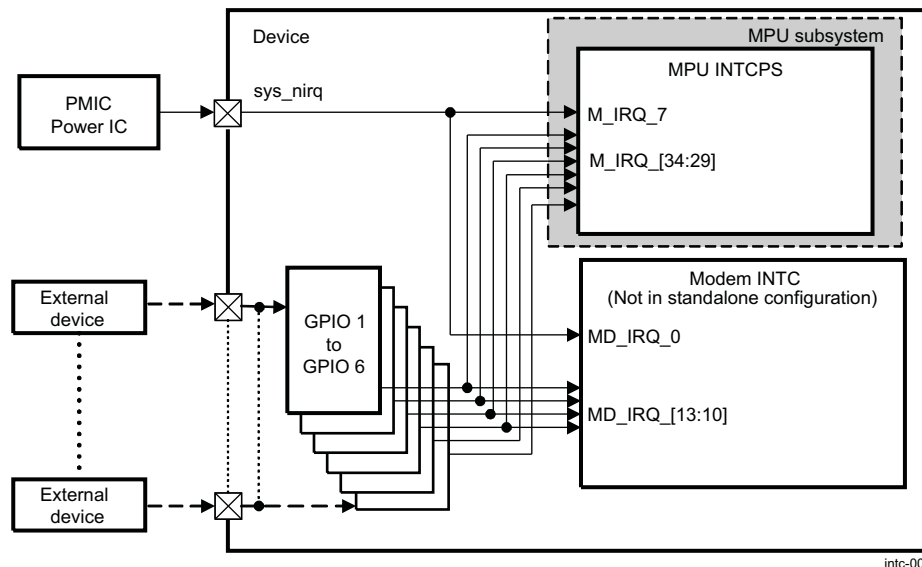

---

- GPIO interrupt inputs:

External devices can also use GPIO modules to generate interrupts to the MPU and the modem. There are six dedicated interrupt lines to the MPU INTC and four dedicated interrupt inputs to the modem INTC. One interrupt line is associated with each GPIO module. Each GPIO module can generate a single interrupt whenever there is at least one event in any one of the configured 32 GPIO inputs. For more information about GPIO features, see [Chapter 24, General-Purpose Interface](#).

Figure 10-2 shows the relationship between the device and external interrupts.

**Figure 10-2. Interrupts From External Devices**

---

**NOTE:** The modem INTC cannot use GPIO5 and GPIO6 as interrupt sources.

---

The features specific to INTCPs are:

- Up to 96 level-sensitive interrupt inputs
- Individual priority (up to 64) for each interrupt input
- Interrupt lines connected to internal module interrupts
- One incoming interrupt line from an external device

**Table 10-2. Hardware and Software Reset**

Type	Name	Source	Activation	Domain
Hardware	CORE_RST	PRCM	Active low	CORE
Software	SOFTRESET	MPU_INTC.INTCPS_SYSCONFIG[1] SOFTRESET bit	Active at 1	MPU INTC internal

### 10.3.1.3 Power Management

The MPU subsystem INTC belongs to the CORE power domain. As part of CORE power domain, it is sensitive to a CORE\_RST issued by the PRCM. For more information about the CORE power domain implementation and CORE\_RST signal, see [Chapter 4, Power, Reset, and Clock Management](#).

The MPU INTC clocks come from the MPU DPLL. For more information about these clocks control, see [Chapter 3, MPU Subsystem](#).

### 10.3.2 Interrupt Request Lines

[Table 10-3](#) lists the incoming and outgoing interrupt lines of the INTCPS.

**Table 10-3. Interrupt Lines Incoming and Outgoing**

Type	Number	Name	Mapping	Comments
Interrupt request inputs	Up to 96	M_IRQ_[95:0]	See <a href="#">Table 10-4</a>	Inputs to INTCPS module, source from various modules.
Interrupt request outputs	2	MPU_INTC_FIQ	MPU_INTC_FIQ	Outgoing to MPU Fast Interrupt
		MPU_INTC_IRQ	MPU_INTC_IRQ	Outgoing to MPU Normal Interrupt

**NOTE:** Interrupt request signals are active at low level.

#### CAUTION

A single interrupt source can be physically mapped to multiple INTCs (MPU subsystem, IVA2.2 subsystem, and modem). With multiple-mapped interrupts, it is strongly recommended each interrupt source be unmasked in only one INTC at a time.

This section gives information about all modules and features in the high-tier device. See [Section 1.5, OMAP35xx Family](#), to check availability of modules and features. Ensure that interrupts of unavailable modules and features are masked in MPU subsystem.

[Table 10-4](#) lists interrupt mappings to the MPU subsystem.

## 10.4 Interrupt Controller Functional Description

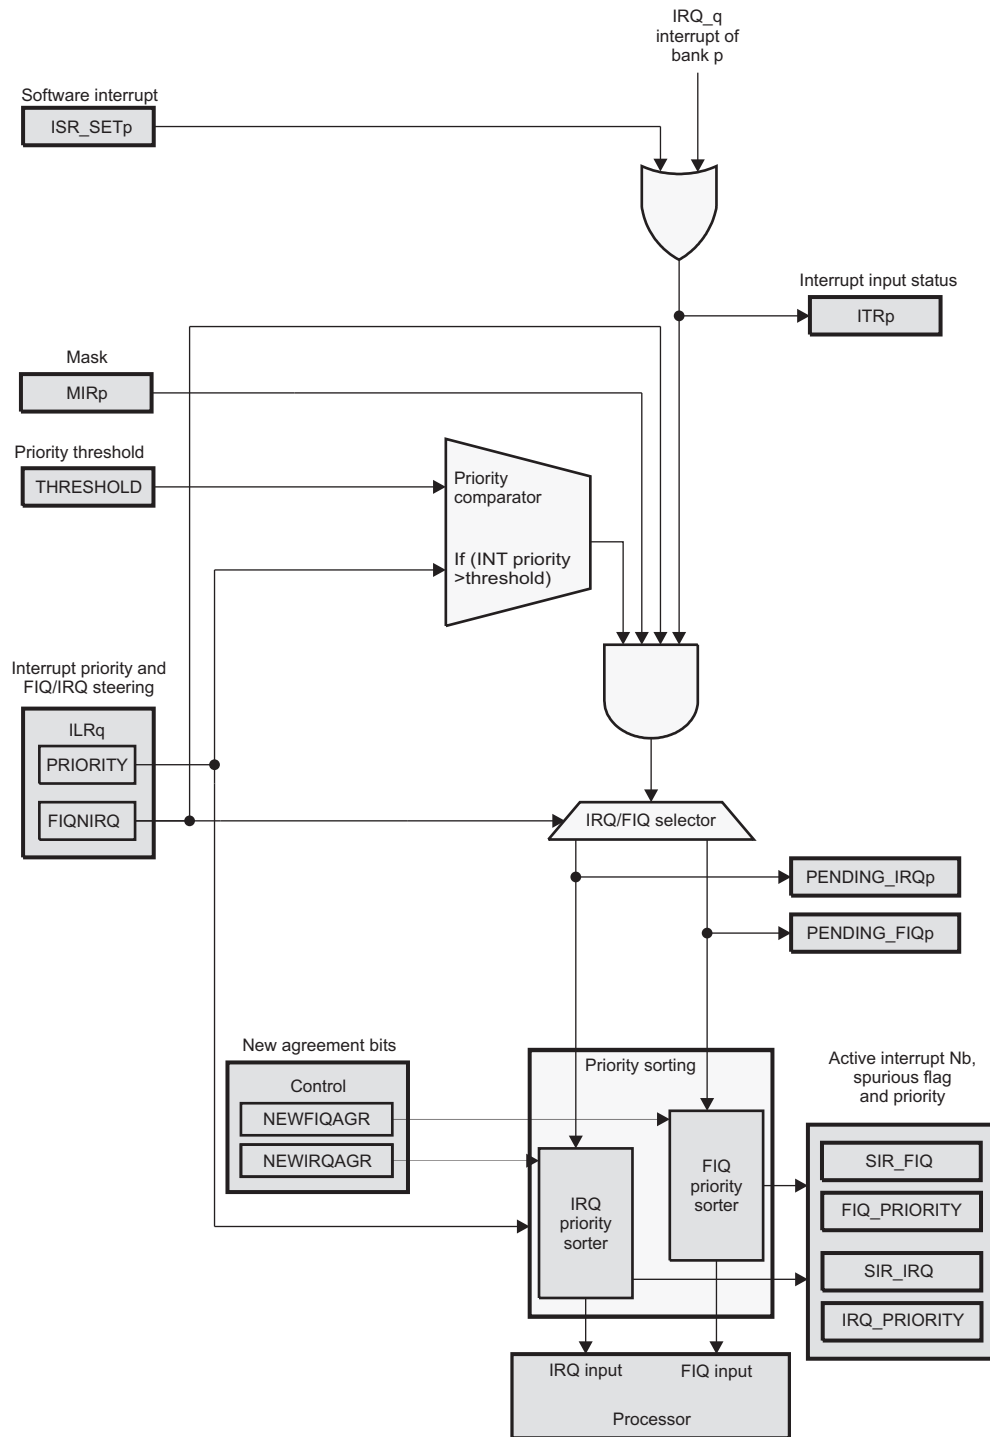

The main features of the INTCPS are:

- Individual priority (up to 64 levels) for each interrupt input
- Ability for each interrupt to be steered to either FIQ or IRQ
- Independent priority sorting for FIQ and IRQ; FIQ sorting is processed concurrently with IRQ sorting.
- Priority masking: Interrupts can be masked based on the priority threshold register.
- Atomic bit set and clear capability for interrupt mask and software interrupt registers
- Power-management and wake-up support
- Auto-idle power-saving support

The INTCPS processes incoming interrupts by masking and priority sorting, then it generates the interrupt requests to the MPU.

[Figure 10-4](#) shows the top-level view of the interrupt processing.

Figure 10-4. Top-Level Block Diagram

intc-004

## 10.4.1 Interrupt Processing

### 10.4.1.1 Input Selection

The INTCPs supports only level-sensitive incoming interrupt detection. A peripheral asserting an interrupt maintains it until software has handled the interrupt and instructed the peripheral to deassert the interrupt.

A software interrupt is generated if the corresponding bit in the MPU\_INTC.INTCPs\_ISR\_SETn register is set (register bank number: n = [0,2] for the MPU subsystem INTCPs, 96 incoming interrupt lines are supported). The software interrupt clears when the corresponding bit in the MPU\_INTC.INTCPs\_ISR\_CLEARn register is written. Typical use of this feature is software debugging.

### 10.4.1.2 Masking

#### 10.4.1.2.1 Individual Masking

Detection of interrupts on each incoming interrupt line can be enabled or disabled independently by the MPU\_INTC.INTCPs\_MIRn interrupt mask register. In response to an unmasked incoming interrupt, the INTCPs can generate one of two types of interrupt requests to the processor:

- IRQ: low-priority interrupt request
- FIQ: fast interrupt request

The type of interrupt request is determined by the MPU\_INTC.INTCPs\_ILRm[0] FIQNIRQ bit (m= [0,95]).

The current incoming interrupt status before masking is readable from the MPU\_INTC.INTCPs\_ITRn register. After masking and IRQ/FIQ selection, and before priority sorting is done, the interrupt status is readable from the MPU\_INTC.INTCPs\_PENDING\_IRQn and MPU\_INTC.INTCPs\_PENDING\_FIQn registers.

#### 10.4.1.2.2 Priority Masking

To enable faster processing of high-priority interrupts, a programmable priority masking threshold is provided (the MPU\_INTC.INTCPs\_THRESHOLD[7:0] PRIORITYTHRESHOLD field). This priority threshold allows preemption by higher priority interrupts; all interrupts of lower or equal priority than the threshold are masked. However, priority 0 can never be masked by this threshold; a priority threshold of 0 is treated the same way as priority 1.

PRIORITY and PRIORITYTHRESHOLD fields values can be set between 0x0 and 0x3F; 0x0 is the highest priority and 0x3F is the lowest priority.

When priority masking is not necessary, a priority threshold value of 0xFF disables the priority threshold mechanism. This value is also the reset default for backward compatibility with previous versions of the INTCPs.

### 10.4.1.3 Priority Sorting

A priority level (0 being the highest) is assigned to each incoming interrupt line. Both the priority level and the interrupt request type are configured by the MPU\_INTC.INTCPs\_ILRm register. If more than one incoming interrupt with the same priority level and interrupt request type occur simultaneously, the highest-numbered interrupt is serviced first.

When one or more unmasked incoming interrupts are detected, the INTCPs separates between IRQ and FIQ using the corresponding MPU\_INTC.INTCPs\_ILRm[0] FIQNIRQ bit. The result is placed in INTCPs\_PENDING\_IRQn or INTCPs\_PENDING\_FIQn

If no other interrupts are currently being processed, INTCPs asserts IRQ/FIQ and starts the priority computation. Priority sorting for IRQ and FIQ can execute in parallel.

Each IRQ/FIQ priority sorter determines the highest priority interrupt number. Each priority number is placed in the corresponding MPU\_INTC.INTCPS\_SIR\_IRQ[6:0] ACTIVEIRQ field or MPU\_INTC.INTCPS\_SIR\_FIQ[6:0] ACTIVEFIQ field. The value is preserved until the corresponding MPU\_INTC.INTCPS\_CONTROL NEWIRQAGR or NEWFIQAGR bit is set.

Once the interrupting peripheral device has been serviced and the incoming interrupt deasserted, the user must write to the appropriate NEWIRQAGR or NEWFIQAGR bit to indicate to the INTCPS the interrupt has been handled. If there are any pending unmasked incoming interrupts for this interrupt request type, the INTCPS restarts the appropriate priority sorter; otherwise, the IRQ or FIQ interrupt line is deasserted.

### 10.4.2 Register Protection

If the MPU\_INTC.INTCPS\_PROTECTION[0] PROTECTION bit is set, access to the INTCPS registers is restricted to the supervisor mode. Access to the MPU\_INTC.INTCPS\_PROTECTION register is always restricted to privileged mode.

### 10.4.3 Module Power Saving

The INTCPS provides an auto-idle function in its three clock domains:

- Interface clock
- Functional clock
- Synchronizer clock

The interface clock auto-idle power-saving mode is enabled if the MPU\_INTC.INTCPS\_SYSCONFIG[0] AUTOIDLE bit is set to 1. When this mode is enabled and there is no activity on the bus interface, the interface clock is disabled internally to the module, thus reducing power consumption. When there is new activity on the bus interface, the interface clock restarts without any latency penalty. After reset, this mode is disabled, by default.

The functional clock auto-idle power-saving mode is enabled if the MPU\_INTC.INTCPS\_IDLE[0] FUNCIDLE bit is set to 0. When this mode is enabled and there is no active interrupt (IRQ or FIQ interrupt being processed or generated) or no pending incoming interrupt, the functional clock is disabled internally to the module, thus reducing power consumption. When a new unmasked incoming interrupt is detected, the functional clock restarts and the INTCPS processes the interrupt. If this mode is disabled, the interrupt latency is reduced by one cycle. After reset, this mode is enabled, by default.

The synchronizer clock allows external asynchronous interrupts to be resynchronized before they are masked. The synchronizer input clock has an auto-idle power-saving mode enabled if the MPU\_INTC.INTCPS\_IDLE[1] TURBO bit is set to 1. If the auto-idle mode is enabled, the standby power is reduced, but the IRQ or FIQ interrupt latency increases from four to six functional clock cycles. This feature can be enabled dynamically according to the requirements of the device. After reset, this mode is disabled, by default.

To reduce power consumption of the modem INTC, which is not use in the stand-alone device, modem INTC clocks must be configured in auto-idle mode. Therefore, both the MPU\_INTC.INTCPS\_SYSCONFIG[0] AUTOIDLE and MPU\_INTC.INTCPS\_IDLE[1] TURBO bits must be set to 1 during initialization.

### 10.4.4 Interrupt Latency

The IRQ/FIQ interrupt generation takes four INTCPS functional clock cycles (plus or minus one cycle) if the MPU\_INTC.INTCPS\_IDLE[1] TURBO bit is set to 0. If the TURBO bit is set to 1, the interrupt generation takes six cycles, but power consumption is reduced while waiting for an interrupt.

These latencies can be reduced by one cycle by disabling functional clock auto-idle (MPU\_INTC.INTCPS\_IDLE[0] FUNCIDLE bit set to 1), but power consumption is increased, so the benefit is minimal. For information about power saving, see [Section 10.4.3](#).

To minimize interrupt latency when an unmasked interrupt occurs, the IRQ or FIQ interrupt is generated before priority sorting completion. The priority sorting takes 10 functional clock cycles, which is less than the minimum number of cycles required for the MPU to switch to the interrupt context after reception of the IRQ or FIQ event.

Any read of the MPU\_INTC.INTCPS\_SIR\_IRQ or MPU\_INTC.INTCPS\_SIR\_FIQ register during the priority sorting process stalls until priority sorting is complete and the relevant register is updated. However, the delay between the interrupt request being generated and the interrupt service routine being executed is such that priority sorting always completes before the MPU\_INTC.INTCPS\_SIR\_IRQ or MPU\_INTC.INTCPS\_SIR\_FIQ register is read.

## 10.5 Interrupt Basic Programming Model

### 10.5.1 Initialization Sequence

1. Program the MPU\_INTC.INTCPS\_SYSCONFIG register: If necessary, enable the interface clock autogating by setting the AUTOIDLE bit.
2. Program the MPU\_INTC.INTCPS\_IDLE register: If necessary, disable functional clock autogating or enable synchronizer autogating by setting the FUNCIDLE bit or TURBO bit accordingly.
3. Program the MPU\_INTC.INTCPS\_ILRm register for each interrupt line: Assign a priority level and set the FIQNFIQ bit for an FIQ interrupt (by default, interrupts are mapped to IRQ and priority is 0x0 [highest]).
4. Program the MPU\_INTC.INTCPS\_MIRn register: Enable interrupts (by default, all interrupt lines are masked).

---

**NOTE:** To program the MPU\_INTC.INTCPS\_MIRn register, the MPU\_INTC.INTCPS\_MIR\_SETn and MPU\_INTC.INTCPS\_MIR\_CLEARn registers are provided to facilitate the masking, even if it is possible for backward-compatibility to write directly to the MPU\_INTC.INTCPS\_MIRn register.

---

### 10.5.2 MPU INTC Processing Sequence

After the MPU\_INTC.INTCPS\_MIRn and MPU\_INTC.INTCPS\_ILRm registers are configured to enable and assign priorities to incoming interrupts, the interrupt is processed as explained in the following subsections.

IRQ and FIQ processing sequences are quite similar, the differences for the FIQ sequence are shown after a '/' character in **bold** characters in the text or the code below.

1. One or more unmasked incoming interrupts (M\_IRQ\_n signals) are received and IRQ or FIQ outputs (MPU\_INTC\_IRQ/**FIQ**) are not currently asserted.
2. If the MPU\_INTC.INTCPS\_ILRm[0] FIQNIRQ bit is set to 0, the MPU\_INTC\_IRQ output signal is generated. If the FIQNIRQ bit is set to 1, the MPU\_INTC\_FIQ output signal is generated.
3. The INTC performs the priority sorting and updates the MPU\_INTC.INTCPS\_SIR\_IRQ[6:0] ACTIVEIRQ /**MPU\_INTC.INTCPS\_SIR\_FIQ[6:0] ACTIVEFIQ** field with the current interrupt number.
4. During priority sorting, if the IRQ/**FIQ** is enabled at the host processor side, the host processor automatically saves the current context and executes the ISR as follows:

---

**NOTE:** The ARM host processor automatically performs the following actions in pseudo code.

---

```

LR = PC + 4                /* return link          */
SPSR = CPSR               /* Save CPSR before execution */
CPSR[5] = 0               /* Execute in ARM state      */
CPSR[7] = 1               /* Disable IRQ                */
CPSR[8] = 1               /* Disable Imprecise Data Aborts */
CPSR[9] = CP15_reg1_EEbit /* Endianness on exception entry */
if interrupt == IRQ then
    CPSR[4:0] = 0b10010    /* Enter IRQ mode           */
    if high vectors configured then
        PC = 0xFFFF0018
    else
        PC = 0x00000018    /* execute interrupt vector */

```

```

else if interrupt == FIQ then
    CPSR[4:0] = 0b10001          /* Enter FIQ mode          */
    CPSR[6] = 1                 /* Disable FIQ           */
    if high vectors configured then
        PC = 0xFFFF001C
    else
        PC = 0x0000001C        /* execute interrupt vector */
endif

```

5. The ISR saves the remaining context, identifies the interrupt source by reading the **ACTIVEIRQ/ACTIVEFIQ** field, and jumps to the relevant subroutine handler as follows:

### CAUTION

The code in steps 5 and 7 is an assembly code compatible with ARM architecture V6 and V7. This code is developed for the Texas Instruments Code Composer Studio tool set. It is a draft version, only tested on an emulated environment.

```

; INTCPS_SIR_IRQ/INTCPS_SIR_FIQ register address
INTCPS_SIR_IRQ_ADDR/INTCPS_SIR_FIQ_ADDR .word 0x48200040/0x48200044

; ACTIVEIRQ bit field mask to get only the bit field
ACTIVEIRQ_MASK .equ 0x7F
_IRQ_ISR/_FIQ_ISR:

    ; Save the critical context
    STMFDP SP!, {R0-R12, LR}          ; Save working registers and the Link register

    MRS R11, SPSR                    ; Save the SPSR into R11

    ; Get the number of the highest priority active IRQ/FIQ
    LDR R10, INTCPS_SIR_IRQ_ADDR/INTCPS_SIR_FIQ_ADDR
    LDR R10, [R10]                   ; Get the INTCPS_SIR_IRQ/INTCPS_SIR_FIQ register
    AND R10, R10, #ACTIVEIRQ_MASK    ; Apply the mask to get the active IRQ number

    ; Jump to relevant subroutine handler
    LDR PC, [PC, R10, lsl #2]        ; PC base address points this instruction + 8

    NOP                               ; To index the table by the PC

    ; Table of handler start addresses
    .word IRQ0handler ;For IRQ0 of BANK0
    .word IRQ1handler
    .word IRQ2handler

```

6. The subroutine handler executes code specific to the peripheral generating the interrupt by handling the event and deasserting the interrupt condition at the peripheral side.

```

; IRQ0 subroutine
IRQ0handler:

    ; Save working registers
    STMFDP SP!, {R0-R1}

    ; Now read-modify-write the peripheral module status register
    ; to de-assert the M_IRQ0 interrupt signal

    ; De-Assert the peripheral interrupt

    MOV R0, #0x7                    ; Mask for 3 flags
    LDR R1, MODULE0_STATUS_REG_ADDR ; Get the address of the module Status Register
    STR R0, [R1]                    ; Clear the 3 flags

```

```

; Restore working registers      LDMFD SP!, {R0-R1}
; Jump to the end part of the ISR
B IRQ_ISR_end/FIQ_ISR_end

```

7. After the return of the subroutine, the ISR sets the **NEWIRQAGR/NEWFIQAGR** bit to enable the processing of subsequent pending **IRQs/FIQs** and to restore ARM context in the following code. Because the writes are posted on an Interconnect bus, to be sure that the preceding writes are done before enabling **IRQs/FIQs**, a Data Synchronization Barrier is used. This operation ensure that the **IRQ/FIQ** line is de-asserted before **IRQ/FIQ** enabling. After that, the INTC processes any other pending interrupts or deasserts the **MPU\_INTC\_IRQ/MPU\_INTC\_FIQ** signal if there is no interrupt.

```

; INTCPS_CONTROL register address
INTCPS_CONTROL_ADDR .word 0x48200048;

NEWIRQAGR/NEWFIQAGR bit mask to set only the NEWIRQAGR/NEWFIQAGR bit
NEWIRQAGR_MASK/NEWFIQAGR_MASK .equ 0x01/0x02

IRQ_ISR_end/FIQ_ISR_end:

; Allow new IRQs/FIQs at INTC side
; The INTCPS_CONTROL register is a write only register so no need to write back others bits

MOV R0, #NEWIRQAGR_MASK/NEWFIQAGR_MASK ; Get the NEWIRQAGR/NEWFIQAGR bit position
LDR R1, INTCPS_CONTROL_ADDR
STR R0, [R1] ; Write the NEWIRQAGR/NEWFIQAGR bit to allow new
IRQs/FIQs

; Data Synchronization Barrier
MOV R0, #0
MCR P15, #0, R0, C7, C10, #4

; restore critical context
MSR SPSR, R1 ; Restore the SPSR from R1
LDMFD SP!, {R0-R12, LR} ; Restore working registers and
Link register

; Return after handling the interrupt
SUBS PC, LR, #4

```

8. After the ISR return, the ARM automatically restores its context as follows:

```

CPSR = SPSR
PC = LR

```

**Figure 10-5** shows the **IRQ/FIQ** processing sequence from the originating device peripheral module to the main program interruption.

**Figure 10-5. IRQ/FIQ Processing Sequence**

108-005

**NOTE:** The differences between the IRQ and the FIQ sequence are highlighted in blue and bold characters.

The priority sorting mechanism is frozen during an interrupt processing sequence. If an interrupt condition occurs during this time, the interrupt is not lost. It is sorted when the **NEWIRQAGR/NEWFIQAGR** bit is set (priority sorting is reactivated).

### 10.5.3 MPU INTC Preemptive Processing Sequence

Preemptive interrupts, also called nested interrupts, can reduce the latencies for higher priority interrupts. A preemptive ISR can be suspended by a higher priority interrupt. Thus, the higher priority interrupt can be served immediately.

Nested interrupts must be used carefully to avoid using corrupted data. Programmers must save corruptible registers and enable IRQ or FIQ at ARM side.

IRQ and FIQ processing sequences are quite similar, the differences for the FIQ sequence are shown after a '/' character in **bold** characters in the text or the code below.

To enable IRQ/**FIQ** preemption by higher priority IRQs/**FIQs**, programers can follow this procedure to write the ISR:

At the beginning of an IRQ/**FIQ** ISR:

1. Save the ARM critical context registers.
2. Save the MPU\_INTC.INTCPS\_THRESHOLD PRIORITYTHRESHOLD field before modifying it.
3. Read the active interrupt priority in the MPU\_INTC.INTCPS\_IRQ\_PRIORITY IRQPRIORITY / **MPU\_INTC.INTCPS\_FIQ\_PRIORITY FIQPRIORITY** field and write it to the PRIORITYTHRESHOLD<sup>(1)</sup> field.
4. Read the active interrupt number in the MPU\_INTC.INTCPS\_SIR\_IRQ[6:0] ACTIVEIRQ / **MPU\_INTC.INTCPS\_SIR\_FIQ[6:0] ACTIVEFIQ** field to identify the interrupt source.
5. Write 1 to the appropriate MPU\_INTC.INTCPS\_CONTROL NEWIRQAGR and <sup>(2)</sup> **NEWFIQAGR** bit while an interrupt is still processing to allow only higher priority interrupts to preempt.
6. Because the writes are posted on an Interconnect bus, to be sure that the preceding writes are done before enabling IRQs/**FIQs**, a Data Synchronization Barrier is used. This operation ensure that the IRQ line is de-asserted before IRQ/**FIQ** enabling.
7. Enable IRQ/**FIQ** at ARM side.
8. Jump to the relevant subroutine handler.

The sample code below shows the previous steps:

#### CAUTION

The code below is an assembly code compatible with ARM architecture V6 and V7. This code is developed for the Texas Instruments Code Composer Studio tool set. It is a draft version, only tested on an emulated environment.

```

; bit field mask to get only the bit field
ACTIVEPRIO_MASK .equ 0x3F

_IRQ_ISR:

    ; Step 1 : Save the critical context
    STMFD SP!, {R0-R12, LR}          ; Save working registers
    MRS R11, SPSR                    ; Save the SPSR into R11

    ; Step 2 : Save the INTCPS_THRESHOLD register into R12
    LDR R0, INTCPS_THRESHOLD_ADDR

```

- <sup>(1)</sup> The priority-threshold mechanism is enabled automatically when writing a priority in the range of 0x00 to 0x3F while reading it from the IRQPRIORITY and FIQPRIORITY fields. Writing a value of 0xFF (reset default) disables the priority-threshold mechanism. Values between 0x3F and 0xFF must not be used. When the hardware-priority threshold is in use, the priorities of interrupts selected as FIQ or IRQ become linked; otherwise, they are independent. When they are linked, all FIQ priorities must be set higher than all IRQ priorities to maintain the relative priority of FIQ over IRQ.
- <sup>(2)</sup> When handling FIQs using the priority-threshold mechanism, both NEWFIQAGR and NEWIRQAGR bits must be written at the same time to ensure that the new priority threshold is applied while an IRQ sort is in progress. This IRQ will not have been seen by the ARM, as it will have been masked on entry to the FIQ ISR. However, the source of the IRQ remains active and it is finally processed when the priority threshold falls to a priority sufficiently low to allow it to be processed. The precaution of writing to New FIQ Agreement is not required during an IRQ ISR, as FIQ sorting is not affected (providing all FIQ priorities are higher than all IRQ priorities).

```

LDR R12, [R0]

; Step 3 : Get the priority of the highest priority active IRQ
LDR R1, INTCPS_IRQ_PRIORITY_ADDR/INTCPS_FIQ_PRIORITY_ADDR
LDR R1, [R1] ; Get the
INTCPS_IRQ_PRIORITY/INTCPS_FIQ_PRIORITY register
AND R1, R1, #ACTIVEPRIO_MASK ; Apply the mask to get the priority of the IRQ

STR R1, [R0] ; Write it to the INTCPS_THRESHOLD register

; Step 4 : Get the number of the highest priority active IRQ
LDR R10, INTCPS_SIR_IRQ_ADDR/INTCPS_SIR_FIQ_ADDR
LDR R10, [R10] ; Get the INTCPS_SIR_IRQ/INTCPS_SIR_FIQ register

AND R10, R10, #ACTIVEIRQ_MASK ; Apply the mask to get the active IRQ number

; Step 5 : Allow new IRQs and FIQs at INTC side
MOV R0, #0x1/0x3 ; Get the NEWIRQAGR and NEWFIQAGR bit position
LDR R1, INTCPS_CONTROL_ADDR
STR R0, [R1] ; Write the NEWIRQAGR and NEWFIQAGR bit

; Step 6 : Data Synchronization Barrier
MOV R0, #0 MCR P15, #0, R0, C7, C10, #4

; Step 7 : Read-modify-write the CPSR to enable IRQs/FIQs at ARM side
MRS R0, CPSR ; Read the status register
BIC R0, R0, #0x80/0x40 ; Clear the I/F bit
MSR CPSR, R0 ; Write it back to enable IRQs

; Step 8 : Jump to relevant subroutine handler
LDR PC, [PC, R10, lsl #2] ; PC base address points this instruction + 8
NOP ; To index the table by the PC

; Table of handler start addresses
.word IRQ0handler ;IRQ0 BANK0
.word IRQ1handler
.word IRQ2handler

```

After the return of the relevant IRQ/FIQ subroutine handle :

1. Disable IRQs/FIQs at ARM side.
2. Restore the MPU\_INTC.INTCPS\_THRESHOLD PRIORITYTHRESHOLD field.
3. Restore the ARM critical context registers.

The sample code below shows the three previous steps:

### CAUTION

The code below is an assembly code compatible with ARM architecture V6 and V7. This code is developed for the Texas Instruments Code Composer Studio tool set. It is a draft version, only tested on an emulated environment.

```

IRQ_ISR_end:

; Step 1 : Read-modify-write the CPSR to disable IRQs/FIQs at ARM side
MRS R0, CPSR ; Read the CPSR
ORR R0, R0, #0x80/0x40 ; Set the I/F bit
MSR CPSR, R0 ; Write it back to disable IRQs

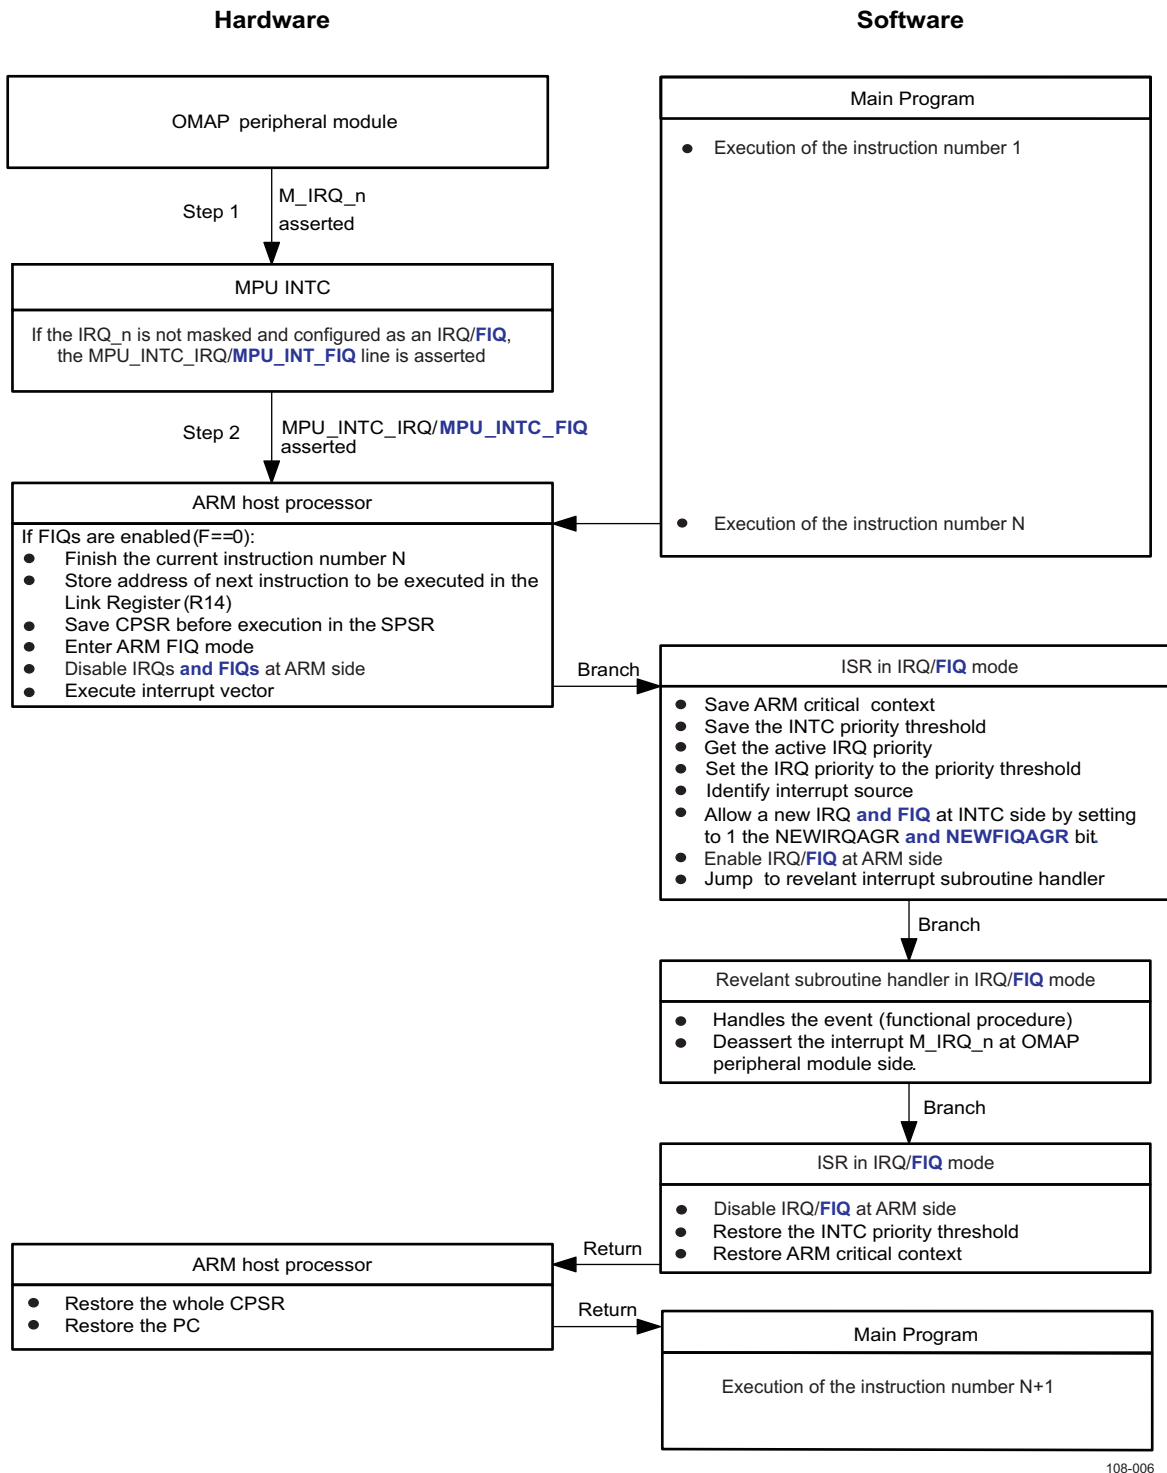

; Step 2 : Restore the INTCPS_THRESHOLD register from R12
LDR R0, INTCPS_THRESHOLD_ADDR
STR R12, [R0]

```

```
; Step 3 : Restore critical context
MSR SPSR, R11                               ; Restore the SPSR from R11
LDMFD SP!, {R0-R12, LR}                     ; Restore working registers and Link register

; Return after handling the interrupt
SUBS PC, LR, #4
```

Figure 10-6 shows the nested IRQ/FIQ processing sequence from the originating device peripheral module to the main program interruption.

**Figure 10-6. Nested IRQ/FIQ Sequence**

108-006

**NOTE:** The differences between the IRQ and the FIQ sequence are highlighted in blue and bold characters.

### 10.5.4 MPU INTC Spurious Interrupt Handling

The spurious flag indicates whether the result of the sorting (a window of 10 INTC functional clock cycles after the interrupt assertion) is invalid. The sorting is invalid if:

- The interrupt that triggered the sorting is no longer active during the sorting.
- A change in the mask has affected the result during the sorting time.

As a result, the values in the MPU\_INTC.INTCPS\_MIRn, MPU\_INTC.INTCPS\_ILRm, or MPU\_INTC.INTCPS\_MIR\_SETn registers must not be changed while the corresponding interrupt is asserted. If these registers are changed within the 10-cycle window after the interrupt assertion, only the active interrupt input that triggered the sort can be masked before its turn in the sort. The resulting values of the following registers become invalid:

- MPU\_INTC.INTCPS\_SIR\_IRQ
- MPU\_INTC.INTCPS\_SIR\_FIQ
- MPU\_INTC.INTCPS\_IRQ\_PRIORITY
- MPU\_INTC.INTCPS\_FIQ\_PRIORITY

This condition is detected for both IRQ and FIQ, and the invalid status is flagged across the SPURIOUSIRQFLAG (see Note 1) and SPURIOUSFIQFLAG (see Note 2) bit fields in the SIR and PRIORITY registers. A 0 indicates valid and a 1 indicates invalid interrupt number and priority. The invalid indication can be tested in software as a false register value.

---

**NOTE:**

1. The MPU\_INTC.INTCPS\_SIR\_IRQ[31:7] SPURIOUSIRQFLAG bit field is a copy of the MPU\_INTC.INTCPS\_IRQ\_PRIORITY[31:7] SPURIOUSIRQFLAG bit field.
  2. The MPU\_INTC.INTCPS\_SIR\_FIQ[31:7] SPURIOUSFIQFLAG bit field is a copy of the MPU\_INTC.INTCPS\_FIQ\_PRIORITY[31:7] SPURIOUSFIQFLAG bit field.
-

## 10.6 Interrupt Controller Register Manual

### 10.6.1 Instance Summary

Table 10-5 lists the base address and address space for the INTC instances.

**Table 10-5. INTC Instance Summary**

Module Name	Base Address	Size
MPU INTC	0x4820 0000	4K bytes
Modem INTC	0x480C 7000	4K bytes

### 10.6.2 Register Summary

#### CAUTION

MPU INTC and Modem INTC registers are limited to 32-bit and 16-bit data accesses; 8-bit data access is not allowed and can corrupt the register content.

In Section 10.6.3, each register from MPU\_INTC.INTCPS\_ITR<sub>n</sub> to MPU\_INTC.INTCPS\_PENDING\_FIQ<sub>n</sub> contains 32 bits, 1 bit for each interrupt (in ascending order: bit 0 of the MPU\_INTC.INTCPS\_ITR0 register applies to interrupt line 0; bit 0 of the MPU\_INTC.INTCPS\_ITR1 register applies to interrupt line 32).

11.3 On-Chip Memory Subsystem .....	1315

## 11.1 General-Purpose Memory Controller

### 11.1.1 General-Purpose Memory Controller Overview

The general-purpose memory controller (GPMC) is the OMAP™2 unified memory controller (UMC) dedicated to interfacing external memory devices:

- Asynchronous SRAM-like memories and application-specific integrated circuit (ASIC) devices
- Asynchronous, synchronous, and page mode (only available in non-muxed mode) burst NOR flash devices
- NAND flash
- Pseudo-SRAM devices

**NOTE:** Page mode is only available in non-muxed mode. The non-muxed mode is described in this chapter even though its use is very limited (address space limited to 2 KBytes).

Figure 11-1 shows the environment of the GPMC.

**Figure 11-1. GPMC Environment**

gpmc-001

### 11.1.1.1 GPMC Features

The GPMC is the OMAP2 16-bit external memory controller. The GPMC data access engine provides a flexible programming model for communication with all standard memories. The GPMC supports various accesses:

- Asynchronous read/write access
- Asynchronous read page access (4, 8, 16 Word16)
- Synchronous read/write access
- Synchronous read/write burst access without wrap capability (4, 8, 16 Word16)
- Synchronous read/write burst access with wrap capability (4, 8, 16 Word16)
- Address/data-multiplexed access
- Little- and big-endian access

The GPMC can communicate with a wide range of external devices:

- External asynchronous or synchronous 8-bit wide memory or device (non-burst device)
- External asynchronous or synchronous 16-bit wide memory or device
- External 16-bit nonmultiplexed device with limited address range (2 Kbytes)
- External 16-bit address/data-multiplexed NOR flash device
- External 8-bit and 16-bit NAND flash device
- External 16-bit pseudo-static random access memory (pSRAM) device

The GPMC supports up to eight chip-select regions of programmable size, and programmable base addresses in a total address space of 1 Gbyte.

### 11.1.2 GPMC Environment

[Figure 11-2](#) and [Figure 11-3](#) show two GPMC external connection options:

- GPMC to 16-bit address/data-multiplexed memory  
[Figure 11-2](#) shows a connection between the GPMC and a 16-bit synchronous address/data-multiplexed external memory device.
- GPMC to 16-bit NAND device  
[Figure 11-3](#) shows a connection between the GPMC and a 16-bit NAND device.

Figure 11-2. GPMC to 16-Bit Address/Data-Multiplexed Memory

**NOTE:** The OMAP device does not provide the A0 byte address line required for random-byte addressable 8-bit wide device interfacing (for multiplexed and nonmultiplexed protocol). Hence, an 8-bit device must be connected to the D[7:0] / gpmc\_d[7:0] data bus (rather than D[15:8] / gpmc\_d[15:8]) of the GPMC controller. This limits the use of 8-bit wide device interfacing to byte-alias access.

Figure 11-3. GPMC to 16-Bit NAND Device

gpmc-003

**NOTE:** The OMAP device does not provide the A0 byte address line required for random-byte addressable 8-bit wide device interfacing (for multiplexed and nonmultiplexed protocol). Hence, an 8-bit device must be connected to the D[7:0]/gpmc\_d[7:0] data bus (rather than D[15:8]/gpmc\_d[15:8]) of the GPMC controller. This limits the use of 8-bit wide device interfacing to byte-alias accesses.

Table 11-1 lists the GPMC subsystem I/O pins.

Table 11-1. GPMC I/O Description

Pin Name	I/O	Description
gpmc_a[10:1]	O	Address
gpmc_d[15:0]	I/O	Data
gpmc_ncs[7:0]	O	Chip-selects (active low)
gpmc_clk	I/O	Clock <sup>(1)</sup>
gpmc_nadv_ale	O	Address valid (active low). Also used as address latch enable (active high) for NAND protocol memories.
gpmc_noe_nre	O	Output enable (active low). Also used as read enable (active low) for NAND protocol memories.
gpmc_nwe	O	Write enable (active low)
gpmc_nbe0_cle	O	Lower-byte enable (active low). Also used as command latch enable for NAND protocol memories.
gpmc_nbe1	O	Byte 1 enable (active low)
gpmc_nwp	O	Write protect (active low)
gpmc_wait[3:0]	I	External wait signal for NOR and NAND protocol memories
gpmc_io_dir	O	gpmc_d[15:0] signal direction control: Low during transmit (for write access: data OUT from GPMC to memory), High during receive (for read access: data IN from memory to GPMC)

<sup>(1)</sup> This output signal is also used as retiming input (the CONTROL\_PADCONF\_x.INPUTENABLE bit must be set to 1).

Table 11-2 shows the use of address and data GPMC controller pins based on the type of external device.

**Table 11-2. GPMC Pin Multiplexing Options**

GPMC Pin	Multiplexed Address Data 16-Bit Device	Nonmultiplexed Address Data 16-Bit Device With LIMITED- ADDRESS Bit Enabled	16-Bit NAND Device	8-Bit NAND Device
gpmc_a[10]	A26	A10	Not used	Not used
gpmc_a[9]	A25	A9	Not used	Not used
gpmc_a[8]	A24	A8	Not used	Not used

gpmc_a[6]	A22	A6	Not used	Not used
gpmc_a[5]	A21	A5	Not used	Not used
gpmc_a[4]	A20	A4	Not used	Not used
gpmc_a[3]	A19	A3	Not used	Not used
gpmc_a[2]	A18	A2	Not used	Not used
gpmc_a[1]	A17	A1	Not used	Not used
gpmc_d[15]	A16/D15	D15	D15	Not used
gpmc_d[14]	A15/D14	D14	D14	Not used
gpmc_d[13]	A14/D13	D13	D13	Not used
gpmc_d[12]	A13/D12	D12	D12	Not used
gpmc_d[11]	A12/D11	D11	D11	Not used
gpmc_d[10]	A11/D10	D10	D10	Not used
gpmc_d[9]	A10/D9	D9	D9	Not used
gpmc_d[8]	A9/D8	D8	D8	Not used
gpmc_d[7]	A8/D7	D7	D7	D7
gpmc_d[6]	A7/D6	D6	D6	D6
gpmc_d[5]	A6/D5	D5	D5	D5
gpmc_d[4]	A5/D4	D4	D4	D4
gpmc_d[3]	A4/D3	D3	D3	D3
gpmc_d[2]	A3/D2	D2	D2	D2
gpmc_d[1]	A2/D1	D1	D1	D1
gpmc_d[0]	A1/D0	D0	D0	D0

Enabling the GPMC.GPMC\_CONFIG[1] LIMITEDADDRESS bit forces A[26:11] to 1 on the GPMC I/O side. Thus, only devices with 2 Kbytes of addressing space can be accessed using gpmc\_a[10:1].

With all device types, the GPMC does not drive unnecessary address lines. They stay at their reset value of 0x00.

Address mapping supports address/data-multiplexed 16-bit wide devices:

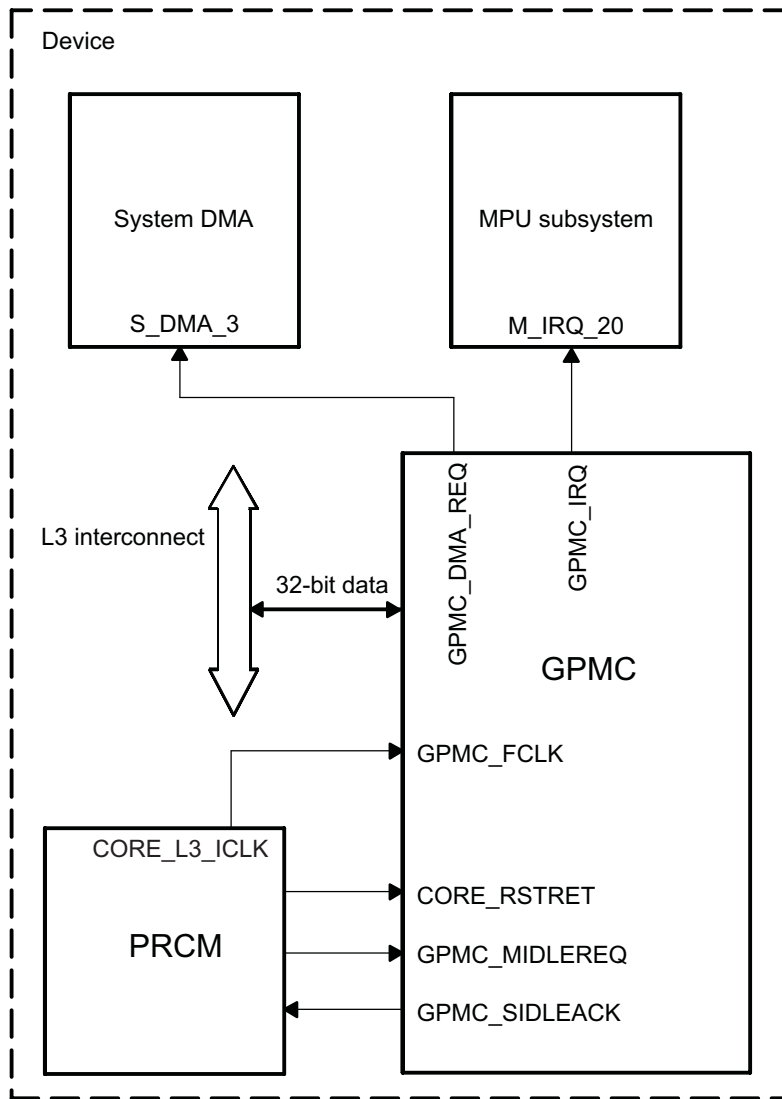

- To minimize the number of IC pins required for the external memory connection, the NOR flash memory controller supports multiplexed address and data memory devices without adding logic externally.
- Multiplexing mode can be selected through the GPMC.GPMC\_CONFIG1\_i[9] MUXADDDATA bit (i = 0 to 7).
- Asynchronous page mode is not supported for multiplexed address and data devices.

### 11.1.3 GPMC Integration

#### 11.1.3.1 Description

Figure 11-4 shows how the GPMC interacts with other modules in the OMAP device.

Figure 11-4. GPMC Integration in the OMAP Device

gpmc-004

### 11.1.3.2 Clocking, Reset, and Power-Management Scheme

#### 11.1.3.2.1 Clocking

The GPMC use a single clock, GPMC\_FCLK, which comes internally from the power, reset, and clock-management (PRCM) module and runs at the L3 interconnect frequency. Its source is the PRCM module, CORE\_L3\_ICLK output. CORE\_L3\_ICLK belongs to the L3 interconnect clock domain.

For details, see [Chapter 4, Power, Reset, and Clock Management](#).

GPMC\_CLK is the external clock provided to the attached synchronous memory or device. The GPMC\_CLK clock frequency is the GPMC\_FCLK clock frequency divided by 1, 2, 3, or 4, depending on the GPMC.GPMC\_CONFIG1\_i[1:0] GPMCFCLKDIVIDER bit field (where i = 0 to 7).

---

**NOTE:** When the GPMC is configured for synchronous mode, the GPMC\_CLK signal (which is an output) must also be set as an input (CONTROL.CONTROL\_PADCONF\_GPMC\_NCS7[24] INPUTENABLE1 = 1). GPMC\_CLK is looped back through the output and input buffers of the corresponding GPMC\_CLK pad at the OMAP boundary. The looped-back clock is used to synchronize the sampling of the memory signals.

---

#### 11.1.3.2.2 Hardware Reset

A global reset of the GPMC occurs through activation of the CORE\_RSTRET signal (CORE power domain) controlled by the Power, Reset and Clock Management module (see [Chapter 4, Power, Reset, and Clock Management](#)).

The CORE\_RSTRET signal is activated during IC global power-on and global warm reset, and it resets the controller state machine and configuration registers.

#### 11.1.3.2.3 Software Reset

GPMC modules can be reset under software control through the GPMC.GPMC\_SYSCONFIG[1] SOFTRESET bit. When software reset bit is set, all registers and the finite state-machine (FSM) are reset immediately and unconditionally. The GPMC\_SYSSTATUS[0] RESETDONE bit can be polled to check reset status.

#### 11.1.3.2.4 Power Domain, Power Saving, and Reset Management

GPMC power is supplied by the CORE power domain, and GPMC power management complies with system power-management guidelines.

The GPMC reduces power consumption through auto-idle mode and the idle request/acknowledge process, both of which are configurable:

- Dynamic auto-idle (configurable through the GPMC.GPMC\_SYSCONFIG[0] AUTOIDLE bit): To reduce power consumption, the GPMC internally disables the functional clock when no requests are pending and no accesses are ongoing.
- Idle request/acknowledge (one of three idle modes configurable through the GPMC.GPMC\_SYSCONFIG[4:3] IDLEMODE field):
  - Force-idle: Immediately on receiving an idle request from the PRCM module, the GPMC sends an idle request/acknowledge to let the PRCM module correctly cut the GPMC source clock.
  - No-idle: The GPMC never goes to idle mode.
  - Smart-idle (strongly recommended): The GPMC goes to idle mode when all ongoing transactions are complete.

For detailed information about power management, see [Chapter 4, Power, Reset, and Clock Management](#).

#### 11.1.3.2.5 Hardware Requests

The GPMC uses two hardware requests as shown in [Figure 11-4](#) :

- One interrupt request goes from GPMC (GPMC\_IRQ) to the microprocessor unit (MPU) subsystem : M\_IRQ\_20.
- One DMA request goes from GPMC (GPMC\_DMA\_REQ) to the system DMA (sDMA) : S\_DMA\_3.

### 11.1.3.3 GPMC Address and Data Bus

The current application supports GPMC connection to address/data-multiplexed memory and a NAND device. Connection to a nonmultiplexed address/data memory is supported with an address range of only 2 Kbytes.

Depending on the GPMC configuration on each chip-select, address and data-bus lines that are not required for a particular access protocol are not updated (changed from current value) and are not sampled when input (input data bus).

The current application supports GPMC connection to address/data-multiplexed memory, address/data-nonmultiplexed memory with limited address (2 Kbytes), and a NAND device:

- When the GPMC.GPMC\_CONFIG[1] LIMITEDADDRESS bit is set to 1, only gpmc\_a[10:1] address lines are used. This limits the memory support to 2K-byte addressable memories.
- For address/data-multiplexed NOR devices, the address is multiplexed on the data bus.
- 8-bit wide NOR devices do not use GPMC I/O: gpmc\_d[15:8] for data (they are used for address if needed).
- 16-bit wide NAND devices do not use GPMC I/O: gpmc\_a[10:1].
- 8-bit wide NAND devices do not use GPMC I/O: gpmc\_a[10:1] and GPMC I/O: gpmc\_d[15:8].

#### **CAUTION**

Before trying to access a chip-select configured with a nonmultiplexed protocol, set the LIMITEDADDRESS bit control.

#### 11.1.3.3.1 GPMC I/O Configuration Setting (in Default Pinout Mode 0)

---

**NOTE:** In this section, the *i* in [GPMC\\_CONFIG1\\_i](#) stands for the GPMC chip-select *i* where *i* = 0 to 7.

---

The address/data-nonmultiplexed device, which is limited to a 2K-byte address range, is selected by programming the following register fields:

- GPMC.GPMC\_CONFIG1\_i[11:10] DEVICETYPE field = 0x00
- GPMC.GPMC\_CONFIG1\_i[9] MUXADDDATA bit = 0
- GPMC.GPMC\_CONFIG[1] LIMITEDADDRESS bit = 1

---

**NOTE:** The LIMITEDADDRESS field applies only to address/data-nonmultiplexed devices; it has no effect on other device types (address/data-multiplexed, NAND).

---

To select the address/data-multiplexed device, program the following register fields:

- GPMC.GPMC\_CONFIG1\_i[11:10] DEVICETYPE field = 0b00
- GPMC.GPMC\_CONFIG1\_i[9] MUXADDDATA bit = 1

To select the NAND device, program the following register field:

- GPMC.GPMC\_CONFIG1\_i[11:10] DEVICETYPE field = 0b10
- GPMC.GPMC\_CONFIG1\_i[9] MUXADDDATA bit = 0

### 11.1.3.3.2 GPMC CS0 Default Configuration at IC Reset

To ensure a correct external boot with a GPMC access from IC reset time on CS0, several external pins are sampled:

- The sys\_boot[4:0] pins (OMAP device boundary) define the sequence of interfaces and devices to use for booting.
- The sys\_boot[5] pin defines which group of booting sequences is preferred: memory booting (sys\_boot[5] = 0) or peripheral booting (sys\_boot[5] = 1).
- Three additional pins are used to configure reset values in the GPMC.GPMC\_CONFIG1\_i register (where i = 0):
  - The bootwaiten input pin (GPMC boundary) enables the monitoring on chip-select 0 of the WAIT pin at IC reset release time for read accesses. The input pin is used to configure the GPMC.GPMC\_CONFIG1\_i[22] WAITREADMONITORING bit (where i = 0). Its value comes from the BOOT\_WAIT\_ENABLE signal generated by the system control module (SCM). When sys\_boot[5:0] = 0b111111, the BOOT\_WAIT\_ENABLE signal is activated, causing the wait pin to be monitored for read access.
  - The bootdevicesize input pin (GPMC boundary) defines the size of the attached device on chip-select 0 and is used to configure the GPMC.GPMC\_CONFIG1\_i[13:12] DEVICESIZE bits (where i = 0). A BOOT\_DEVICE\_SIZE signal is propagated from the SCM. Its value is fixed at 0x1 at IC reset, causing a 16-bit wide external memory to be used.
  - The cs0muxdevice input pin (GPMC boundary) selects whether the attached device to chip-select 0 is a multiplexed address and data device or not. The input pin is used to configure the GPMC.GPMC\_CONFIG1\_i[9] MUXADDDATA bit (where i = 0). A CS0\_MUX\_DEVICE signal is propagated from the SCM. Its value is fixed at 0x1 at IC reset, causing the attached device to be address/data-multiplexed.
  - The waitselectpin input pin selects the WAIT signal at IC reset release time between WAIT0 input pin or WAIT1 input pin. At IC reset release time, these two pins have different polarity.

#### CAUTION

Using the internal boot code, the entire CS0 configuration can be modified before the first CS0 access. This modification of internal boot code is necessary for two external devices:

- NAND device attached to CS0
- Nonmultiplexed 2-Kbyte address range device attached to CS0

At reset time, the IC may boot from the internal ROM or from the memory attached to the GPMC chip-select 0. This selection is made outside the GPMC.

Reset values of the timing control parameters are defined to cope with direct boot on address and data multiplexed NOR Flash device, on non-multiplexed NOR Flash device or on any asynchronous device with large timing margins assuming a low GPMC\_FCLK frequency (for example, 19.2Mhz) at boot time.

## 11.1.4 GPMC Functional Description

### 11.1.4.1 Description

As [Figure 11-5](#) shows, the GPMC consists of six blocks:

- L3 interconnect port interface
- Address decoder, GPMC configuration, and chip-select configuration register file
- Access engine
- Prefetch and write-posting engine
- Error correction code engine (ECC)
- External device/memory port interface

Figure 11-5. GPMC Functional Diagram

gpmc-005

The GPMC can access various external devices through the L3 Interconnect. The flexible programming model allows a wide range of attached device types and access schemes.

Based on the programmed configuration bit fields stored in the GPMC registers, the GPMC is able to generate all control signals timing depending on the attached device and access type.

Given the chip-select decoding and its associated configuration registers, the GPMC selects the appropriate device type control signals timing.

#### 11.1.4.2 L3 Interconnect Interface

The GPMC L3 interconnect interface is a pipelined interface including an 8 × 32-bit word write buffer. Any OMAP system host can issue external access requests through the GPMC.

The OMAP system can issue the following requests through this interface:

- One 8-bit/16-bit/32-bit interconnect access (read/write)
- Two incrementing 32-bit interconnect accesses (read/write)
- Two wrapped 32-bit interconnect accesses (read/write)
- Four incrementing 32-bit interconnect accesses (read/write)
- Four wrapped 32-bit interconnect accesses (read/write)
- Eight incrementing 32-bit interconnect accesses (read/write)
- Eight wrapped 32-bit interconnect accesses (read/write)

Only linear burst transactions are supported; interleaved burst transactions are not supported. Only power-of-two-length precise bursts  $2 \times 32$ ,  $4 \times 32$ , or  $8 \times 32$  with the burst base address aligned on the total burst size are supported (this limitation applies to incrementing bursts only).

This interface also provides one interrupt and one DMA request line, for specific event control.

It is recommended to program the ATTACHEDDEVICEPAGELENGTH field ([GPMC\\_CONFIG1\\_i\[24:23\]](#)) according to the effective attached device page length and to enable WRAPBURST bit ([GPMC\\_CONFIG1\\_i\[31\]](#)) if the attached device supports wrapping burst.

However, it is possible to emulate wrapping burst on a non-wrapping memory by providing relevant addresses within the page or splitting transactions. Bursts larger than the memory page length are chopped into multiple bursts transactions. Due to the alignment requirements, a page boundary is never crossed.

#### 11.1.4.3 Address Decoder, GPMC Configuration, and Chip-Select Configuration Register File

Address-decoding logic selects for chip-selects according to the address request and the content of the chip-select base address register file, which includes a set of global GPMC configuration registers and eight sets of chip-select configuration registers.

The GPMC configuration register file is memory-mapped and can be read or written with byte, 16-bit word, or 32-bit word accesses. The register file should be configured as a noncacheable, nonbufferable region to prevent any desynchronization between host execution (write request) and the completion of register configuration (write completed with register updated). [Section 11.1.7](#) of this chapter provides the GPMC register locations. For the map of GPMC memory locations, see [Chapter 2, Memory Mapping](#).

After the chip-select is configured, the access engine accesses the external device, drives the external interface control signals, and applies the interface protocol based on user-defined timing parameters and settings.

#### 11.1.4.4 Error Correction Code Engine

The GPMC includes an error correction code (ECC) calculation engine that allows ECC calculation during data read or data program (write) operations. Two ECC algorithms are available depending on [GPMC\\_ECC\\_CONFIG\[16\]](#) ECCALGORITHM settings: Hamming code or BCH code (Bose-Chaudhuri-Hocquenghem).

The GPMC does not directly handle the error code correction itself. During writes, the GPMC computes parity bits. During reads, the GPMC provides enough information for the processor to correct errors without reading the data buffer all over again.

The Hamming code ECC is based on a 2-dimensional (row and column) bit parity accumulation. This parity accumulation is either accomplished on the programmed number of bytes or Word16s read from the memory device, or written to the memory device in stream mode.

Because the ECC engine includes only one accumulation context, it can be allocated to only one chip-select at a time through the GPMC [GPMC\\_ECC\\_CONFIG\[3:1\]](#) ECCCS bit field.

See [Section 11.1.5.14.3](#) for more information on ECC calculation.

#### 11.1.4.5 Prefetch and Write-Posting Engine

The prefetch and write-posting engine is a simplified embedded-access requester that presents requests to the access engine on a user-defined chip-select target. The access engine interleaves these requests with any request coming from the L3 interface; as a default the prefetch and write-posting engine has the lowest priority.

The prefetch and write-posting engine is dedicated to data-stream access (as opposed to random data access); thus, it is primarily dedicated to NAND support. The engine does not include an address generator; the request is limited to chip-select target identification. It includes a 64-byte FIFO associated with a DMA request synchronization line, for optimal DMA-based use.

For more information about prefetch and write-posting engine programming, see [Section 11.1.5.14.4, Prefetch and Write-Posting Engine](#).

#### 11.1.4.6 External Device/Memory Port Interface

The external port interface controls all address, data, and control signals required for communication with GPMC-supported devices and memories.

### 11.1.5 GPMC Basic Programming Model

The GPMC basic programming model offers maximum flexibility to support various access protocols for each of the eight configurable chip-selects. Use optimal chip-select settings, based on the characteristics of the external device:

- Different protocols can be selected to support generic asynchronous or synchronous random-access devices (NOR flash, SRAM) or to support specific NAND devices.
- The address and the data bus can be multiplexed on the same external bus.
- Read and write access can be independently defined as asynchronous or synchronous.
- System requests (byte, Word16, burst) are performed through single or multiple accesses. External access profiles (single, multiple with optimized burst length, native- or emulated-wrap) are based on external device characteristics (supported protocol, bus width, data buffer size, native-wrap support).
- System burst read or write requests are synchronous-burst (multiple-read or multiple-write). When neither burst nor page mode is supported by external memory or ASIC devices, system burst read or write requests are translated to successive single synchronous or asynchronous accesses (single reads or single writes). 8-bit wide devices are supported only in single-synchronous or asynchronous read or write mode.
- To simulate a programmable internal-wait state, an external wait pin can be monitored to dynamically control external access at the beginning (initial access time) of and during a burst access.

Each control signal is controlled independently for each chip-select. The internal functional clock of the GPMC (GPMC\_FCLK) is used as a time reference to specify the following:

- Read- and write-access duration
- Most GPMC external interface control-signal assertion and deassertion times
- Data-capture time during read access
- External wait-pin monitoring time
- Duration of idle time between accesses, when required

#### 11.1.5.1 Chip-Select Base Address and Region Size Configuration

Any external memory or ASIC device attached to the GPMC external interface can be accessed by any OMAP system host within the GPMC 1-GB contiguous address space. For details, see [Chapter 2, Memory Mapping](#).

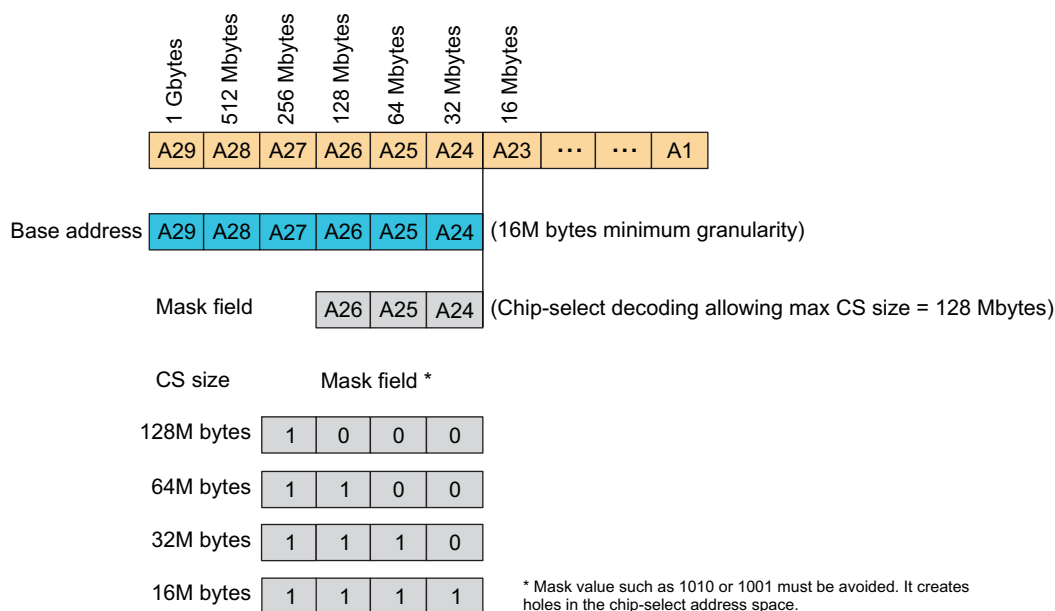

The GPMC 1-GB address space can be divided into a maximum of eight chip-select regions with programmable base address and programmable CS size. The CS size is programmable from 16MB to 128MB (must be a power-of-2) and is defined by the mask field. Attached memory smaller than the programmed CS region size is accessed through the entire CS region (aliasing).

Each chip-select has a 6-bit base address encoding and a 4-bit decoding mask, which must be programmed according to the following rules:

- The programmed chip-select region base address must be aligned on the chip-select region size address boundary and is limited to a power-of-2 address value. During access decoding, the register base address value is used for address comparison with the address-bit line mapping as described in [Figure 11-6](#) (with A0 as the OMAP system byte-address line). Base address is programmed through the `GPMC_CONFIG7_i[5:0]` BASEADDRESS bit field
- The register mask is used to exclude some address lines from the decoding. A register mask bit field set to 0 suppresses the associated address line from the address comparison (incoming address bit line is don't care). The register mask value must be limited to the subsequent value, based on the desired chip-select region size. Any other value has an undefined result. When multiple chip-select regions with overlapping addresses are enabled concurrently, access to these chip-select regions is cancelled and a GPMC access error is posted. The mask field is programmed through the `GPMC_CONFIG7_i[11:8]` MASKADDRESS bit field.

**Figure 11-6. Chip-Select Address Mapping and Decoding Mask**

gpmc-006

Chip-select configuration (base and mask address or any protocol and timing settings) must be performed while the associated chip-select is disabled through the GPMC.`GPMC_CONFIG7_i[6]` CSVALID bit (where *i* stands for the GPMC chip-select value, *i* = 0 to 7). In addition, a chip-select configuration can be disabled only if there is no ongoing access to that chip-select. This requires activity monitoring of the prefetch or write-posting engine if the engine is active on the chip-select. Also, the write buffer state must be monitored to wait for any posted write completion to the chip-select.

Conversely, before trying to access a chip-select, software must ensure that the chip-select is enabled. To account for prefetch engine effects, after the chip-select-enable instruction, an NOP instruction (equivalent to 64 bits) must be executed before the chip-select is accessed.

Any access attempted to a nonvalid GPMC address region (CSVALID disabled or address decoding outside a valid chip-select region) is not propagated to the external interface and a GPMC access error is posted. In case of chip-selects overlapping, an error is generated and no access will occur on either chip-select.

Chip-select 0 is the only chip-select region enabled after either a power-up or a GPMC reset.

### CAUTION

Although the GPMC interface can drive up to 8 chip-selects, the frequency specified for this interface is for a specific load. If this load is exceeded, the maximum frequency cannot be reached. One solution is to implement a board with buffers, to allow the slowest device to maintain the total load on the lines.

## 11.1.5.2 Access Protocol Configuration

### 11.1.5.2.1 Supported Devices

The access protocol of each chip-select can be independently specified through the GPMC.GPMC\_CONFIG1\_*i*[11:10] DEVICETYPE parameter (where *i* = 0 to 7) for:

- Random-access synchronous or asynchronous memory like NOR flash, SRAM
- NAND flash asynchronous devices

---

**NOTE:** NAND flash interfacing requires the parameter settings of generic chip-select 0. For more information about the NAND flash GPMC basic programming model and NAND support, see [Section 11.1.5.14, NAND Device Basic Programming Model](#), and [Section 11.1.5.14.1, NAND Memory Device in Byte or Word 16 Stream Mode](#).

---

### 11.1.5.2.2 Access Size Adaptation and Device Width

Each chip-select can be independently configured through the GPMC.GPMC\_CONFIG1\_*i*[13:12] DEVICESIZE field (*i* = 0 to 7) to interface with a 16-bit wide device or an 8-bit wide device. System requests with data width greater than the external device data bus width are split into successive accesses according to both the external device data-bus width and little-endian data organization.

---

**NOTE:** The OMAP device does not provide the A0 byte address line required for random-byte addressable 8-bit wide device interfacing (for both multiplexed and nonmultiplexed protocol). It limits the use of 8-bit wide device interfacing to byte-alias accesses. This limitation is not applicable to NAND device interfacing (8-bit wide or 16-bit wide devices).

---

### 11.1.5.2.3 Address/Data-Multiplexing Interface

For random synchronous or asynchronous memory interfacing (DEVICETYPE = 0b00), an address- and data-multiplexing protocol can be selected through the GPMC.GPMC\_CONFIG1\_*i*[9] MUXADDDATA bit (*i* = 0 to 7). The nADV signal must be used as the external device address latch control signal. For the associated chip-select configuration, nADV assertion and deassertion time and nOE assertion time must be set to the appropriate value to meet the address latch setup/hold time requirements of the external device. See [Section 11.1.3, GPMC Integration](#).

---

**NOTE:** This address/data-multiplexing interface is not applicable to NAND device interfacing. NAND devices require a specific address, command, and data multiplexing protocol. See [Section 11.1.5.14, NAND Device Basic Programming Model](#).

---

### 11.1.5.2.4 Address and Data Bus

See [Section 11.1.3.3, GPMC Address and Data Bus](#).

### 11.1.5.2.5 Asynchronous and Synchronous Access

For each chip-select configuration, the read access can be specified as either asynchronous or synchronous access through the GPMC.GPMC\_CONFIG1\_][29] READTYPE bit (i = 0 to 7). For each chip-select configuration, the write access can be specified as either synchronous or asynchronous access through the GPMC.GPMC\_CONFIG1\_][27] WRITETYPE bit (i = 0 to 7).

Asynchronous and synchronous read (write) access time and related control signals are controlled through timing parameters that refer to GPMC\_FCLK. The primary difference of synchronous mode is the availability of a configurable clock interface (GPMC\_CLK) to control the external device. Synchronous mode also affects data-capture and wait-pin monitoring schemes in read access.

For details about asynchronous and synchronous access, see the descriptions of GPMC\_CLK, RdAccessTime, WrAccessTime, and wait-pin monitoring.

For more information about timing-parameter settings, see the sample timing diagrams in this chapter.

---

**NOTE:** The address bus and nBE[1:0] are fixed for the duration of a synchronous burst read access, but they are updated for each beat of an asynchronous page-read access.

---

### 11.1.5.2.6 Page and Burst Support

Each chip-select can be configured to process system single or burst requests into successive single accesses or asynchronous page/synchronous burst accesses, with appropriate access size adaptation.

Depending on the external device page or burst capability, read and write accesses can be independently configured through the GPMC. The GPMC\_CONFIG1\_][30] READMULTIPLE and GPMC\_CONFIG1\_][28] WRITMULTIPLE bits (i = 0 to 7) are associated with the READTYPE and WRITETYPE parameters.

---

**NOTE:**

- Asynchronous write page mode is not supported.
  - 8-bit wide device support is limited to nonburstable devices (READMULTIPLE and WRITEMULTIPLE are don't care).
  - Not applicable to NAND device interfacing.
- 

### 11.1.5.2.7 System Burst Versus External Device Burst Support

The OMAP system can issue the following requests to the GPMC:

- Byte, Word16, Word32 requests (byte enable controlled). This is always a single request from the interconnect point of view.
- Incrementing fixed-length bursts of two words, four words, and eight words
- Wrapped (critical word access first) fixed-length burst of two, four, or eight words

To process a system request with the optimal protocol, the READMULTIPLE (and READTYPE) and WRITEMULTIPLE (and WRITETYPE) parameters must be set according to the burstable capability (synchronous or asynchronous) of the attached device.

The GPMC access engine issues only fixed-length burst. The maximum length that can be issued is defined per CS by the GPMC.GPMC\_CONFIG1\_][24:23] ATTACHEDDEVICEPAGELENGTH field (i = 0 to 7). When the ATTACHEDDEVICEPAGELENGTH value is less than the system burst request length (including the appropriate access size adaptation according to the device width), the GPMC splits the system burst request into multiple burst beats. Within the specified 4-, 8-, or 16-word value, the ATTACHEDDEVICEPAGELENGTH field value must correspond to the maximum-length burst supported by the memory device configured in fixed-length burst mode (as opposed to continuous burst mode).

To get optimal performance from memory devices that natively support 16 Word16-length-wrapping burst capability (critical word access first), the ATTACHEDDEVICEPAGELENGTH parameter must be set to 16 words and the GPMC.GPMC\_CONFIG1\_i[31] WRAPBURST bit (i = 0 to 7) must be set to 1. Similarly DEVICEPAGELENGTH is set to 4 and 8 for memories supporting respectively 4 and 8 Word16-length-wrapping burst.

When the memory device does not offer (or is not configured to offer) native 16 Word16-length-wrapping burst, the WRAPBURST parameter must be cleared, and the GPMC access engine emulates the wrapping burst by issuing the appropriate burst sequences according to the ATTACHEDDEVICEPAGELENGTH value.

When the memory device does not support native-wrapping burst, there is usually no difference in behavior between a fixed burst length mode and a continuous burst mode configuration (except for a potential power increase from a memory-speculative data prefetch in a continuous burst read). However, even though continuous burst mode is compatible with GPCM behavior, because the GPMC access engine issues only fixed-length burst and does not benefit from continuous burst mode, it is best to configure the memory device in fixed-length burst mode.

The memory device maximum-length burst (configured in fixed-length burst wrap or nonwrap mode) usually corresponds to the memory device data buffer size. Memory devices with a minimum of 16 half-word buffers are the most appropriate (especially with wrap support), but memory devices with smaller buffer size (4 or 8) are also supported, assuming that the GPMC.GPMC\_CONFIG1\_i[24:23] ATTACHEDDEVICEPAGELENGTH field is set accordingly to 4 or 8 words.

The OMAP system issues only requests with addresses or starting addresses for nonwrapping burst requests; that is, the request size boundary is aligned. In case of an eight-word-wrapping burst, the wrapping address always occurs on the eight-words boundary. As a consequence, all words requested must be available from the memory data buffer when the buffer size is equal to or greater than the ATTACHEDDEVICEPAGELENGTH value. This usually means that data can be read from or written to the buffer at a constant rate (number of cycles between data) without wait states between data accesses. If the memory does not behave this way (nonzero wait state burstable memory), wait-pin monitoring must be enabled to dynamically control data-access completion within the burst beat.

---

**NOTE:** When the system burst request length is less than the ATTACHEDDEVICEPAGELENGTH value, the GPMC proceeds with the required accesses.

---

### 11.1.5.3 Timing Setting

The GPMC is a signal generator that offers the maximum flexibility to support various access protocols. Most of the timing parameters of the protocol access used by the GPMC to communicate with attached memories or devices are programmable on a chip-select basis. Assertion and deassertion times of control signals are defined to match the attached memory or device timing specifications and to get maximum performance during accesses. For example, the timing diagram in [Figure 11-7](#) shows an asynchronous single-read access performed on an asynchronous device. For more information about GPMC\_CLK and GPMC\_FCLK, see [Section 11.1.5.3.6](#).

**Figure 11-7. Asynchronous Single Read on a Nonmultiplexed Address/Data Device**

gpmc-007

### 11.1.5.3.1 Read Cycle Time and Write Cycle Time (RDCYCLETIME/WRCYCLETIME)

The GPMC.GPMC\_CONFIG5\_i[4:0] RDCYCLETIME and GPMC.GPMC\_CONFIG5\_i[12:8] WRCYCLETIME fields ( $i = 0$  to 7) define the address bus and byte enables valid times for read and write accesses. To ensure a correct duty cycle of GPMC\_CLK between accesses, RDCYCLETIME and WRCYCLETIME are expressed in GPMC\_FCLK cycles and must be multiples of the GPMC\_CLK cycle.

When either RDCYCLETIME or WRCYCLETIME completes, if they are not already deasserted, all control signals (NCS, nADV/ALE, nOE/RE, nWE, and BE0/CLE) are deasserted to their reset values, regardless of their deassertion time parameters.

An exception to this forced deassertion occurs when a pipelined request to the same chip-select or to a different chip-select is pending. In such a case, it is not necessary to deassert a control signal with deassertion time parameters equal to the cycle-time parameter. This exception to forced deassertion prevents any unnecessary glitchy transition. This requirement also applies to BE signals, thus avoiding an unnecessary BE glitch transition when pipelining requests.

If no inactive cycles are required between successive accesses to the same or to a different chip-select (GPMC.GPMC\_CONFIG6\_i[7] CYCLE2CYCLESAMECSSEN = 0 or GPMC.GPMC\_CONFIG6\_i[6] CYCLE2CYCLEDIFFCSSEN = 0, where  $i = 0$  to 7), and if assertion-time parameters associated with the pipelined access are equal to 0, asserted control signals (nCS, nADV/ALE, nBE0/CLE, nWE, and nOE/RE) are kept asserted. This applies to any read/write to read/write access combination.

If inactive cycles are inserted between successive accesses, that is, CYCLE2CYCLESAMECSSEN = 1 or CYCLE2CYCLEDIFFCSSEN = 1, the control signals are forced to their respective default reset values for the number of GPMC\_FCLK cycles defined in CYCLE2CYCLEDELAY:

- The RDCYCLETIME and WRCYCLETIME bit fields are programmable in the

GPMC.GPMC\_CONFIG5\_i register, i = 0 to 7.

- The RDCYCLETIME and WRCYCLETIME bit fields can be set from 0 to 31 GPMC\_FCLK cycles with a granularity of 1 for GPMC.GPMC\_CONFIG1\_i[4] TIMEPARAGRANULARITY set to 0.
- The RDCYCLETIME and WRCYCLETIME bit fields can be set from 0 to 62 GPMC\_FCLK cycles with a granularity of 2 for GPMC.GPMC\_CONFIG1\_i[4] TIMEPARAGRANULARITY set to 1.

### 11.1.5.3.2 nCS: Chip-Select Signal Control Assertion/Deassertion Time (CSONTIME/CSRDOFFTIME/CSWROFFTIME/CSEXTRADELAY)

The GPMC.GPMC\_CONFIG2\_i[3:0] CSONTIME field (where i = 0 to 7) defines the nCS signal-assertion time relative to the start access time. It is common for read and write accesses.

For a read access, the GPMC.GPMC\_CONFIG2\_i[12:8] CSRDOFFTIME field defines the nCS signal deassertion time relative to start access time.

For a write access, the GPMC.GPMC\_CONFIG2\_i[20:16] CSWROFFTIME field defines the nCS signal deassertion time relative to start access time.

CSONTIME, CSRDOFFTIME and CSWROFFTIME parameters are applicable to synchronous and asynchronous modes. CSONTIME can be used to control an address and byte enable setup time before chip-select assertion. CSRDOFFTIME and CSWROFFTIME can be used to control an address and byte enable hold time after chip-select deassertion.

nCS signal transitions as controlled through CSONTIME, CSRDOFFTIME, and CSWROFFTIME can be delayed by half a GPMC\_FCLK period by enabling the GPMC.GPMC\_CONFIG2\_i[7] CSEXTRADELAY bit. This half of a GPMC\_FCLK period provides more granularity on the nCS assertion and deassertion time to guarantee proper setup and hold time relative to GPMC\_CLK. CSEXTRADELAY is especially useful in configurations where GPMC\_CLK and GPMC\_FCLK have the same frequency, but can be used for all GPMC configurations. If asserted, CSEXTRADELAY applies to all parameters controlling nCS transitions.

The CSEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than the nCS signal-deassertion time, including the extra half-GPMC\_FCLK-period delay.

### 11.1.5.3.3 nADV/ALE: Address Valid/Address Latch Enable Signal Control Assertion/Deassertion Time (ADVONTIME/ADVRDOFFTIME/ADVWROFFTIME/ADVEXTRADELAY)

The GPMC.GPMC\_CONFIG3\_i[3:0] ADVONTIME field (where i = 0 to 7) defines the nADV/ALE signal-assertion time relative to start access time. It is common to read and write accesses.

For a read access, the GPMC.GPMC\_CONFIG3\_i[12:8] ADVRDOFFTIME field defines the nADV/ALE signal-deassertion time relative to start access time.

For a write access, the GPMC.GPMC\_CONFIG3\_i[20:16] ADVWROFFTIME field defines the nADV/ALE signal-deassertion time relative to start access time.

ADVONTIME can be used to control an address and byte enable valid setup time control before nADV/ALE assertion. ADVRDOFFTIME and ADVWROFFTIME can be used to control an address and byte enable valid hold time control after nADV/ALE de-assertion. ADVRDOFFTIME and ADVWROFFTIME are applicable to both synchronous and asynchronous modes.

nADV/ALE signal transitions as controlled through ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME can be delayed by half a GPMC\_FCLK period by enabling the GPMC.GPMC\_CONFIG3\_i[7] ADVEXTRADELAY bit. This half of a GPMC\_FCLK period provides more granularity on nADV/ALE assertion and deassertion time to guarantee proper setup and hold time relative to GPMC\_CLK. The ADVEXTRADELAY configuration parameter is especially useful in configurations where GPMC\_CLK and GPMC\_FCLK have the same frequency, but can be used for all GPMC configurations. If asserted, ADVEXTRADELAY applies to all parameters controlling nADV/ALE transitions.

ADVEXTRADELAY must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than nADV/ALE signal-deassertion time, including the extra half-GPMC\_FCLK-period delay.

See [Section 11.1.5.14](#) for more details about ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME use for command (CLE) and address latch enable (ALE) use for a NAND flash interface.

#### 11.1.5.3.4 nOE/nRE: Output Enable/Read Enable Signal Control Assertion/Deassertion Time (OEONTIME/OEOFFTIME/OEEXTRADELAY)

The GPMC.GPMC\_CONFIG4\_i[3:0] OEONTIME field (where i = 0 to 7) defines the nOE/nRE signal assertion time relative to start access time. It is applicable only to read accesses.

The GPMC.GPMC\_CONFIG4\_i[12:8] OEOFFTIME field defines the nOE/nRE signal deassertion time relative to start access time. It is applicable only to read accesses.

OEONTIME and OEOFFTIME parameters are applicable to synchronous and asynchronous modes. OEONTIME can be used to control an address and byte enable valid setup time control before nOE/nRE assertion. OEOFFTIME can be used to control an address and byte enable valid hold time control after nOE/nRE assertion.

The nOE/RE signal transitions as controlled through OEONTIME, and OEOFFTIME can be delayed by half a GPMC\_FCLK period by enabling the GPMC.GPMC\_CONFIG4\_i[7] OEEXTRADELAY bit. This half of a GPMC\_FCLK period provides more granularity on nOE/RE assertion and deassertion time to guaranty proper setup and hold time relative to GPMC\_CLK. If asserted, OEEXTRADELAY applies to all parameters controlling nOE/nRE transitions.

OEEXTRADELAY must be used carefully, to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program RDCYCLETIME and WRCYCLETIME to be greater than nOE/RE signal-deassertion time, including the extra half-GPMC\_FCLK-period delay.

nOE/nRE is not asserted during a write cycle.

---

**NOTE:** When the GPMC generates a read access to an address-/data-multiplexed device, it drives the address bus until nOE assertion time.

---

#### 11.1.5.3.5 nWE: Write Enable Signal Control Assertion/Deassertion Time (WEONTIME/WEOFFTIME/WEEXTRADELAY)

The GPMC.GPMC\_CONFIG4\_i[19:16] WEONTIME field (where i = 0 to 7) defines the nWE signal-assertion time relative to start access time. It applies only to write accesses.

The GPMC.GPMC\_CONFIG4\_i[28:24] WEOFFTIME field defines the nWE signal-deassertion time relative to start access time. It applies only to write accesses.

WEONTIME can be used to control an address and byte enable valid setup time control before nWE assertion. WEOFFTIME can be used to control an address and byte enable valid hold time control after nWE assertion.

nWE signal transitions as controlled through WEONTIME, and WEOFFTIME can be delayed by half a GPMC\_FCLK period by enabling the GPMC.GPMC\_CONFIG4\_i[23] WEEXTRADELAY bit. This half of a GPMC\_FCLK period provides more granularity on nWE assertion and deassertion time to guaranty proper setup and hold time relative to GPMC\_CLK. If asserted, WEEXTRADELAY applies to all parameters controlling nWE transitions.

The WEEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the WRCYCLETIME bit field to be greater than the nWE signal-deassertion time, including the extra half-GPMC\_FCLK-period delay.

nWE is not asserted during a read cycle.

### 11.1.5.3.6 GPMC\_CLK

GPMC\_CLK is the external clock provided to the attached synchronous memory or device.

- The GPMC\_CLK clock frequency is the GPMC\_FCLK functional clock frequency divided by 1, 2, 3, or 4, depending on the GPMC.GPMC\_CONFIG1\_i[1:0] GPMCFCLKDIVIDER bit field (where i = 0 to 7), with a guaranteed 50-percent duty cycle.
- The GPMC\_CLK clock is only activated when the access in progress is defined as synchronous (read or write access).
- The GPMC.GPMC\_CONFIG1\_i[26:25] CLKACTIVATIONTIME field (i = 0 to 7) defines the number of GPMC\_FCLK cycles from start access time to GPMC\_CLK activation.
- The GPMC\_CLK clock is stopped when cycle time completes and is asserted low between accesses.
- The GPMC\_CLK clock is kept low when access is defined as asynchronous.
- When cycle time completes, the GPMC\_CLK may be high because of the GPMCFCLKDIVIDER bit field. To ensure correct stoppage of the GPMC\_CLK clock within the 50-percent required duty cycle, it is the user's responsibility to extend the RDCYCLETIME or WRCYCLETIME value.
- When the GPMC is configured for synchronous mode, the GPMC\_CLK signal (which is an output) must also be set as an input (CONTROL.CONTROL\_PADCONF\_GPMC\_NCS7[24] INPUTENABLE1 = 1). GPMC\_CLK is looped back through the output and input buffers of the corresponding GPMC\_CLK pad at the OMAP boundary. The looped-back clock is used to synchronize the sampling of the memory signals.

---

**NOTE:** To ensure a correct external clock cycle, the following rules must be applied:

- $(RDCYCLETIME - CLKACTIVATIONTIME)$  must be a multiple of  $(GPMCFCLKDIVIDER + 1)$ .
  - The PAGEBURSTACCESSTIME value must be a multiple of  $(GPMCFCLKDIVIDER + 1)$ .
- 

### 11.1.5.3.7 GPMC\_CLK and Control Signals Setup and Hold

Control-signal transition (assertion and deassertion) setup and hold values with respect to the GPMC\_CLK edge can be controlled in the following ways:

- For the GPMC\_CLK signal, the GPMC.GPMC\_CONFIG1\_i[26:25] CLKACTIVATIONTIME field (i = 0 to 7) allows setup and hold control of control-signal assertion time.
- The use of a divided GPMC\_CLK allows setup and hold control of control-signal assertion and deassertion times.
- When GPMC\_CLK runs at the GPMC\_FCLK frequency so that GPMC\_CLK edge and control-signal transitions refer to the same GPMC\_FCLK edge, the control-signal transitions can be delayed by half of a GPMC\_FCLK period to provide minimum setup and hold times. This half-GPMC\_FCLK delay is enabled with the CSEXTRADelay, ADVEXTRADelay, OEEXTRADelay, or WEEXTRADelay parameter. This delay must be used carefully to prevent control-signal overlap between successive accesses to different chip-selects. This implies that the RDCYCLETIME and WRCYCLETIME are greater than the last control-signal deassertion time, including the extra half-GPMC\_FCLK cycle.

### 11.1.5.3.8 Access Time (RDACCESSTIME / WRACCESSTIME)

The read access time and write access time durations can be programmed independently allowing nOE and GPMC data capture timing parameters to be independent of nWE and memory device data capture timing parameters.

RDACCESSTIME is programmed in the GPMC.GPMC\_CONFIG5\_i[20:16] bit field (i = 0 to 7).

WRACCESSTIME is programmed in the GPMC.GPMC\_CONFIG6\_i[28:24] bit field (i = 0 to 7).

RDACCESSTIME and WRACCESSTIME can be set from 0 to 31 GPMC\_FCLK cycles with a granularity of one (GPMC\_CONFIG1\_i[4] TIMEPARAGRANULARITY = 0).

RDACCESSTIME and WRACCESSTIME can be set from 0 to 62 GPMC\_FCLK cycles with a granularity of two (GPMC\_CONFIG1\_i[4] TIMEPARAGRANULARITY = 1).

### 11.1.5.3.8.1 Access Time on Read Access

In asynchronous read mode, for single and paged accesses, RDACCESSTIME field ( $i = 0$  to 7) defines the number of GPMC\_FCLK cycles from start access time to the GPMC\_FCLK rising edge used for the first data capture. RDACCESSTIME must be programmed to the rounded greater GPMC\_FCLK cycle value of the read access time of the attached memory device.

In synchronous read mode, for single or burst accesses, RDACCESSTIME defines the number of GPMC\_FCLK cycles from start access time to the GPMC\_FCLK rising edge corresponding to the GPMC\_CLK rising edge used for the first data capture.

GPMC\_CLK which is sent to the memory device for synchronization with the GPMC controller, is internally retimed to correctly latch the returned data. RDCYCLETIME must be greater than RDACCESSTIME in order to let the GPMC latch the last return data using the internally retimed GPMC\_CLK.

The external WAIT signal can be used in conjunction with RDACCESSTIME to control the effective GPMC data-capture GPMC\_FCLK edge on read access in both asynchronous mode and synchronous mode. For details about wait monitoring, see [Section 11.1.5.4](#).

### 11.1.5.3.8.2 Access Time on Write Access

In asynchronous write mode, the GPMC\_CONFIG6\_j[28:24] WRACCESSTIME timing parameter is not used to define the effective write access time. Instead, it is used as a WAIT invalid timing window, and must be set to a correct value so that the gpmc\_wait pin is at a valid state two GPMC\_CLK cycles before WRACCESSTIME completes. For details about wait monitoring, see [Section 11.1.5.4](#).

In synchronous write mode, for single or burst accesses, WRACCESSTIME defines the number of GPMC\_FCLK cycles from start access time to the GPMC\_CLK rising edge used by the memory device for the first data capture.

The external WAIT signal can be used in conjunction with WRACCESSTIME to control the effective memory device data capture GPMC\_CLK edge for a synchronous write access. For details about wait monitoring, see [Section 11.1.5.4](#).

### 11.1.5.3.9 Page Burst Access Time (PAGEBURSTACCESSTIME)

PAGEBURSTACCESSTIME is programmed in the GPMC.GPMC\_CONFIG5\_i[27:24] bit field ( $i = 0$  to 7). PAGEBURSTACCESSTIME can be set from 0 to 15 GPMC\_FCLK cycles with a granularity of one (GPMC.GPMC\_CONFIG1\_i[4] TIMEPARAGRANULARITY set to 0), or from 0 to 30 GPMC\_FCLK cycles with a granularity of two (TIMEPARAGRANULARITY set to 1).

#### 11.1.5.3.9.1 Page Burst Access Time on Read Access

In asynchronous page read mode, the delay between successive word captures in a page is controlled through the PAGEBURSTACCESSTIME bit field. The PAGEBURSTACCESSTIME parameter must be programmed to the rounded greater GPMC\_FCLK cycle value of the read access time of the attached device.

In synchronous burst read mode, the delay between successive word captures in a burst is controlled through the PAGEBURSTACCESSTIME field.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective GPMC data capture GPMC\_FCLK edge on read access. For details about wait monitoring, see [Section 11.1.5.4](#).

#### 11.1.5.3.9.2 Page Burst Access Time on Write Access

Asynchronous page write mode is not supported. PAGEBURSTACCESSTIME is irrelevant in this case.

In synchronous burst write mode, PAGEBURSTACCESSTIME controls the delay between successive memory device word captures in a burst.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective memory-device data capture GPMC\_CLK edge in synchronous write mode. For details about wait monitoring, see [Section 11.1.5.4](#).

### 11.1.5.3.10 Bus Keeping Support

At the end-cycle time of a read access, if no other access is pending, the GPMC drives the bus with the last data read after RDCYCLETIME completion time to prevent bus floating and reduce power consumption.

After a write access, if no other access is pending, the GPMC keeps driving the data bus after WRCYCLETIME completes with the same data to prevent bus floating and power consumption.

### 11.1.5.4 WAIT Pin Monitoring Control

GPMC access time can be dynamically controlled using an external gpmc\_wait pin when the external device access time is not deterministic and cannot be defined and controlled only using the GPMC internal RDACCESSTIME, WRACCESSTIME and PAGEBURSTACCESSTIME wait state generator.

The GPMC four input wait pins: gpmc\_wait3, gpmc\_wait2, gpmc\_wait1, and gpmc\_wait0. These four pins allow direct plugin and control of external devices with different wait-pin polarity. They also allow the overlap of wait-pin assertion from different devices without affecting access to devices for which the wait pin is not asserted.

- The GPMC.GPMC\_CONFIG1\_i[17:16] WAITPINSELECT field (i = 0 to 7) selects which input gpmc\_wait pin is used for the device attached to the corresponding chip-select.
- The polarity of the wait pin is defined through the WAITxPINPOLARITY bit of the GPMC.GPMC\_CONFIG register. A wait pin configured to be active low means that low level on the WAIT signal indicates that the data is not ready and that the data bus is invalid. When WAIT is inactive, data is valid.

The GPMC access engine can be configured by CS to monitor the wait pin of the external memory device or not, based on the access type: read or write.

- The GPMC.GPMC\_CONFIG1\_i[22] WAITREADMONITORING bit defines whether the wait pin should be monitored during read accesses or not.
- The GPMC.GPMC\_CONFIG1\_i[21] WAITWRITEMONITORING bit defines whether the wait pin should be monitored during write accesses or not.

The GPMC access engine can be configured to monitor the wait pin of the external memory device asynchronously or synchronously with the GPMC\_CLK clock, depending on the access type: synchronous or asynchronous (the GPMC.GPMC\_CONFIG1\_i[29] READTYPE and GPMC.GPMC\_CONFIG1\_i[27] WRITETYPE bits).

#### 11.1.5.4.1 Wait Monitoring During an Asynchronous Read Access

When wait-pin monitoring is enabled for read accesses (WAITREADMONITORING), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the wait-deasserted state.

During asynchronous read accesses with wait-pin monitoring enabled, the wait pin must be at a valid level (asserted or deasserted) for at least two GPMC clock cycles before RDACCESSTIME completes, to ensure correct dynamic access-time control through wait-pin monitoring. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

In this context, RDACCESSTIME is used as a WAIT invalid timing window and is set to such a value that the wait pin is at a valid state two GPMC clock cycles before RDACCESSTIME completes.

Similarly, during a multiple-access cycle (for example, asynchronous read page mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-deasserted state. Wait-monitoring pipelining is also applicable to multiple accesses (access within a page).

- WAIT monitored as active freezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as asserted extends the current access time in the page. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as inactive completes the

current access time and starts the next access phase in the page. The data bus is considered valid, and data are captured during this clock cycle. In case of a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their related control timing value and according to the CYCLETIME counter status.

When a delay larger than two GPMC clocks must be observed between wait-pin deactivation time and data valid time (including the required GPMC and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data-capture time and the effective unlock of the CYCLETIME counter. This extra delay can be programmed in the GPMC.GPMC\_CONFIG1\_i[19:18] WAITMONITORINGTIME field (i = 0 to 7).

**NOTE:**

- The WAITMONITORINGTIME parameter does not delay the wait-pin active or inactive detection, nor does it modify the two GPMC clocks pipelined detection delay.
- This extra delay is expressed as a number of GPMC\_CLK clock cycles, even though the access is defined as asynchronous, and no GPMC\_CLK clock is provided to the external device. Still, GPMCFCLKDIVIDER is used as a divider for the GPMC clock, so it must be programmed to define the correct WAITMONITORINGTIME delay.

Figure 11-8 shows wait behavior during an asynchronous single read access.

**Figure 11-8. Wait Behavior During an Asynchronous Single Read Access (GPMCFCLKDivider = 1)**

**NOTE:** The WAIT signal is active low. WAITMONITORINGTIME = 00, 01.

#### 11.1.5.4.2 Wait Monitoring During an Asynchronous Write Access

When wait-pin monitoring is enabled for write accesses (GPMC.GPMC\_CONFIG1\_i[21] WAITWRITEMONITORING bit = 0x1), the WAIT-invalid timing window is defined by the WRACCESSTIME field. WRACCESSTIME must be set so that the wait pin is at a valid state two GPMC clock cycles before WRACCESSTIME completes. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

- WAIT monitored as active freezes the CYCLETIME counter. This informs the GPMC that the data bus is not captured by the external device. The control signals are kept in their current state. The data bus still drives the data.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. This informs that the data bus is correctly captured by the external device. All signals, including the data bus, are controlled according to their related control timing value and to the CYCLETIME counter status.

When a delay larger than two GPMC clock cycles must be observed between wait-pin deassertion time and the effective data write into the external device (including the required GPMC data setup time and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data write time into the external device and the effective unfreezing of the CYCLETIME counter. This extra delay can be programmed in the GPMC.GPMC\_CONFIG1\_i[19:18] WAITMONITORINGTIME fields (i = 0 to 7).

---

**NOTE:**

- The WAITMONITORINGTIME parameter does not delay the wait-pin assertion or deassertion detection, nor does it modify the two GPMC clock cycles pipelined detection delay.
  - This extra delay is expressed as a number of GPMC\_CLK clock cycles, even though the access is defined as synchronous, and even though no clock is provided to the external device. Still, GPMC\_CONFIG1\_i[1:0] GPMCFCLKDIVIDER is used as a divider for the GPMC clock and so it must be programmed to define the correct WAITMONITORINGTIME delay.
- 

#### 11.1.5.4.3 Wait Monitoring During a Synchronous Read Access

During synchronous accesses with wait-pin monitoring enabled, the wait pin is captured synchronously with GPMC\_CLK, using the rising edge of this clock.

The WAIT signal can be programmed to apply to the same clock cycle it is captured in. Alternatively, it can be sampled one or two GPMC\_CLK cycles ahead of the clock cycle it applies to. This pipelining is applicable to the entire burst access, and to all data phase in the burst access. This WAIT pipelining depth is programmed in the GPMC.GPMC\_CONFIG1\_i[19:18] WAITMONITORINGTIME field (where i = 0 to 7), and is expressed as a number of GPMC\_CLK clock cycles.

In synchronous mode, when wait-pin monitoring is enabled (GPMC.GPMC\_CONFIG1\_i[22] WAITREADMONITORING bit), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the WAIT deasserted-state detection.

Depending on the programmed WAITMONITORINGTIME value, the wait pin should be at a valid level, either asserted or deasserted:

- In the same clock cycle the data is valid if WAITMONITORINGTIME = 0 ( at RDACCESSTIME completion)
- In the WAITMONITORINGTIME × (GPMCFCLKDIVIDER + 1) GPMC\_FCLK clock cycles before RDACCESSTIME completion if WAITMONITORINGTIME ≠ 0

Similarly, during a multiple-access cycle (burst mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-inactive state. The Wait pipelining depth programming applies to the whole burst access.

- WAIT monitored as active freezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in a lock state), WAIT monitored as active extends the current access time in the burst. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.

- WAIT monitored as inactive unfreezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in lock state), WAIT monitored as inactive completes the current access time and starts the next access phase in the burst. The data bus is considered valid, and data are captured during this clock cycle. In a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their relative control timing value and the CYCLETIME counter status.

Figure 11-9 shows wait behavior during a synchronous read burst access.

**Figure 11-9. Wait Behavior During a Synchronous Read Burst Access**

**NOTE:** The WAIT signal is active low. WAITMONITORINGTIME = 00, 01.

gpmc-009

#### 11.1.5.4.4 Wait Monitoring During a Synchronous Write Access

During synchronous accesses with wait-pin monitoring enabled (the WAITWRITEMONITORING bit), the wait pin is captured synchronously with GPMC\_CLK, using the rising edge of this clock.

If enabled, external wait-pin monitoring can be used in combination with WRACCESSTIME to control the effective memory device GPMC\_CLK capture edge.

Wait-monitoring pipelining depth is similar to synchronous read access:

- At WRACCESSTIME completion if WAITMONITORINGTIME = 0
- The WAITMONITORINGTIME × (GPMCFCLKDIVIDER + 1) GPMC\_FCLK cycles before WRACCESSTIME completion if WAITMONITORINGTIME ≠ 0.

Wait-monitoring pipelining definition applies to whole burst accesses:

- WAIT monitored as active freezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as active indicates that the data bus is not being captured by the external device. Control signals are kept in their current state. The data bus is kept in its current state.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as inactive indicates the effective data capture of the bus by the external device and starts the next access of the burst. In case of a single access or if this was the last access in a multiple access cycle, all signals, including the data bus, are controlled according to their related control timing value and the CYCLETIME counter status.

---

**NOTE:** Wait monitoring is supported for all configurations except for [GPMC\\_CONFIG1\\_i\[19:18\]](#) WAITMONITORINGTIME = 0x 0 (where i = 0 to 7) for write bursts with a clock divider of 1 or 2 ([GPMC\\_CONFIG1\\_i\[1:0\]](#) GPMCFCLKDIVIDER bit field equal to 0x0 or 0x1, respectively).

---

#### **11.1.5.4.5 WAIT With NAND Device**

For details about the use of the wait pin for communication with a NAND flash external device, see [Section 11.1.5.14.2, NAND Device-Ready Pin](#).

#### **11.1.5.4.6 Idle Cycle Control Between Successive Accesses**

##### **11.1.5.4.6.1 Bus Turnaround (BUSTURNAROUND)**

To prevent data-bus contention, an access that follows a read access to a slow memory/device (that is, control the nCS/nOE de-assertion to data bus in high-impedance delay) must be delayed.

The bus turnaround is a time-out counter starting after nCS or nOE de-assertion time (whichever occurs first) and delays the next access start-cycle time. It is programmed through the GPMC.[GPMC\\_CONFIG6\\_i\[3:0\]](#) BUSTURNAROUND bit field (where i = 0 to 7).

After a read access to a chip-select with a non zero BUSTURNAROUND, the next access is delayed until the BUSTURNAROUND delay completes, if the next access is one of the following:

- A write access to any chip-select (same or different from the chip-select data was read from)
- A read access to a different chip-select from the chip-select data was read access from
- A read or write access to a chip-select associated with an address/data-multiplexed device

Another way to prevent bus contention is to define an earlier nCS or nOE deassertion time for slow devices or to extend the value of RDCYCLETIME. Doing this prevents bus contention, but affects all accesses of this specific chip-select.

##### **11.1.5.4.6.2 Idle Cycles Between Accesses to Same Chip-Select (CYCLE2CYCLESAMEECSEN, CYCLE2CYCLEDELAY)**

Some devices require a minimum chip-select signal inactive time between accesses. The GPMC.[GPMC\\_CONFIG6\\_i\[7\]](#) CYCLE2CYCLESAMEECSEN bit (i = 0 to 7) enables insertion of a minimum number of GPMC\_FCLK cycles, defined by the GPMC.[GPMC\\_CONFIG6\\_i\[11:8\]](#) CYCLE2CYCLEDELAY field, between successive accesses of any type (read or write) to the same chip-select.

If CYCLE2CYCLESAMEECSEN is enabled, any subsequent access to the same chip-select is delayed until its CYCLE2CYCLEDELAY completes. The CYCLE2CYCLEDELAY counter starts when CSRDOFFTIME/CSWROFFTIME completes.

The same applies to successive accesses occurring during Word32 or burst accesses split into successive single accesses when the single-access mode is used (`GPMC_CONFIG1_i[30] READMULTIPLE = 0` or `GPMC_CONFIG1_i[28] WRITEMULTIPLE = 0`).

All control signals are kept in their default states during these idle GPMC\_FCLK cycles. This prevents back-to-back accesses to the same chip-select without idle cycles between accesses.

#### 11.1.5.4.6.3 Idle Cycles Between Accesses to Different Chip-Select (CYCLE2CYCLEDIFFCSEN, CYCLE2CYCLEDELAY)

Because of the pipelined behavior of the system, successive accesses to different chip-selects can occur back-to-back with no idle cycles between accesses. Depending on the control signals (nCS, nADV/ALE, nBE0/CLE, nOE/RE, nWE) assertion and de-assertion timing parameters and on the IC timing parameters, some control signals assertion times may overlap between the successive accesses to different CS. Similarly, some control signals (WE, OE/RE) may not respect required transition times.

To work around the overlapping and to observe the required control-signal transitions, a minimum of CYCLE2CYCLEDELAY inactive cycles is inserted between the access being initiated to this chip-select and the previous access ending for a different chip-select. This applies to any type of access (read or write).

If `GPMC_CONFIG6_i[6] CYCLE2CYCLEDIFFCSEN` is enabled, the chip-select access is delayed until CYCLE2CYCLEDELAY cycles have expired since the end of a previous access to a different chip-select. CYCLE2CYCLEDELAY count starts at CSRDOFFTIME/CSWROFFTIME completion. All control signals are kept inactive during the idle GPMC\_FCLK cycles.

---

**NOTE:** CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDIFFCSEN should be set in the `GPMC_CONFIG6_i` registers to insert idle cycles between accesses on this chip-select and after accesses to a different chip-select, respectively.

The CYCLE2CYCLEDELAY delay runs in parallel with the BUSTURNAROUND delay. BUSTURNAROUND is a timing parameter defined for the ending chip-select access, whereas CYCLE2CYCLEDELAY is a timing parameter defined for starting chip-select access. The effective minimum delay between successive accesses is based on the larger delay timing parameter and on the access type combination, since bus turnaround does not apply to all access types. See [Section 11.1.5.4.6.1](#) for more details on bus turnaround.

---

Table 11-3 describes the configuration required for idle cycle insertion.

**Table 11-3. Idle Cycle Insertion Configuration**

1st Access Type	BUSTURN AROUND Timing Parameter	Second Access Type	Chip-Select	Add/Data Multiplexed	CYCLE2 CYCLE SAMECSEN Parameter	CYCLE2 CYCLE DIFFCSEN Parameter	Idle Cycle Insertion Between the Two Accesses
R/W	= 0	R/W	Any	Any	0	x	No idle cycles are inserted if the two accesses are well pipelined.
R	> 0	R	Same	Nonmuxed	x	0	No idle cycles are inserted if the two accesses are well pipelined.
R	> 0	R	Different	Nonmuxed	0	0	BTA cycles are inserted.
R	> 0	R/W	Any	Muxed	0	0	BTA cycles are inserted.
R	> 0	W	Any	Any	0	0	BTA cycles are inserted.
W	> 0	R/W	Any	Any	0	0	No idle cycles are inserted if the two accesses are well pipelined.
R/W	= 0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted.
R/W	= 0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted.

**Table 11-3. Idle Cycle Insertion Configuration (continued)**

1st Access Type	BUSTURN AROUND Timing Parameter	Second Access Type	Chip-Select	Add/Data Multiplexed	CYCLE2 CYCLE SAMECSEN Parameter	CYCLE2 CYCLE DIFFCSEN Parameter	Idle Cycle Insertion Between the Two Accesses
R/W	> 0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is max (BUSTURNAROUND, CYCLE2CYCLEDELAY).
R/W	> 0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is maximum (BUSTURNAROUND, CYCLE2CYCLEDELAY).

#### 11.1.5.4.7 Slow Device Support (TIMEPARAGRANULARITY Parameter)

All access-timing parameters can be multiplied by 2 by setting the GPMC.GPMC\_CONFIG1\_i[4] TIMEPARAGRANULARITY bit (where i stands for the GPMC chip-select value, i = 0 to 7). Increasing all access timing parameters allows support of slow devices.

#### 11.1.5.5 gpmc\_io\_dir Pin

The gpmc\_io\_dir pin is used to control I/O direction on the GPMC data bus gpmc\_d[15:0]. Depending on top-level pad multiplexing, this signal can be output and used externally to the OMAP device, if required.

The gpmc\_io\_dir pin is low during transmit (OUT) and high during receive (IN).

For write accesses, the gpmc\_io\_dir pin stays OUT from start-cycle time to end-cycle time.

For read accesses, the gpmc\_io\_dir pin goes from OUT to IN at nOE assertion time and stays IN until:

- BUSTURNAROUND is enabled:
  - The gpmc\_io\_dir pin goes from IN to OUT at end-cycle time plus programmable bus turnaround time.
- BUSTURNAROUND is disabled:
  - After an asynchronous read access, the gpmc\_io\_dir pin goes from IN to OUT at RDACCESSTIME + 1 GPMC\_FCLK cycle or when RDCYCLETIME completes, whichever occurs last.
  - After a synchronous read access, the gpmc\_io\_dir pin goes from IN to OUT at RDACCESSTIME + 2 GPMC\_FCLK cycles or when RDCYCLETIME completes, whichever occurs last.

Because of the bus-keeping feature of the GPMC, after a read or write access and with no other accesses pending, the default value of the gpmc\_io\_dir pin is OUT (see [Section 11.1.5.3.10, Bus Keeping Support](#)).

To prevent unnecessary toggling, the gpmc\_io\_dir pin stays IN between two successive read accesses to a nonmultiplexed device (address mapping supports nonmultiplexed 16-bit wide devices with limited address (2 Kbytes)).

[Figure 11-10](#) shows address mapping in nonmultiplexed mode with a limited address range (A[10:1]).

#### 11.1.5.6 Reset

No reset signal is sent to the external memory device by the GPMC. The PRCM specifications provide more information about external-device reset.

The PRCM module provides an input pin, global\_rst\_n, to the GPMC:

- The global\_rst\_n pin is activated during OMAP warm reset and cold reset.
- The global\_rst\_n pin initializes the internal state-machine and the internal configuration registers.

#### 11.1.5.7 WRITE PROTECT (nWP)

When connected to the attached memory device, the WRITE PROTECT signal can enable or disable the lockdown function of the attached memory.

The gpmc\_nwp output pin value is controlled through the GPMC.GPMC\_CONFIG[4] WRITEPROTECT bit, which is common to all CS.

#### 11.1.5.8 BYTE ENABLE (nBE1/nBE0)

BYTE ENABLE signals (nBE1/nBE0) are:

- Valid (asserted or nonasserted according to the incoming system request) from access start to access completion for asynchronous and synchronous single accesses
- Asserted low from access start to access completion for asynchronous and synchronous multiple read accesses
- Valid (asserted or nonasserted, according to the incoming system request) synchronously to each written data for synchronous multiple write accesses

#### 11.1.5.9 Asynchronous Access Description

In asynchronous operations:

- GPMC\_CLK is not provided outside the GPMC.
- GPMC\_CLK is kept low.

##### 11.1.5.9.1 Asynchronous Single Read

##### 11.1.5.9.1.1 Asynchronous Single Read Operation on a Nonmultiplexed Device

Figure 11-10 shows an asynchronous single read operation on a nonmultiplexed device.

**Figure 11-10. Asynchronous Single Read on an Address/Data-Nonmultiplexed Device**

gpmc-010

In the following section *i* stands for the chip-select number, *i* = 0 to 7.

- GPMC.GPMC\_CONFIG[1] LIMITEDADDRESS set to 1 (A26-A11 are not modified during an external memory access)
- GPMC.GPMC\_CONFIG1\_i register settings:
  - GPMC\_CONFIG1\_i[30] READMULTIPLE bit at 0 (read single access)
  - GPMC\_CONFIG1\_i[29] READTYPE bit at 0 (asynchronous read)
  - GPMC\_CONFIG1\_i[9] MUXADDDATA bit at 0 (non multiplexed device)
- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC\_CONFIG2\_i[3:0] CS ONTIME field. It controls the address setup time to nCS assertion.
  - nCS deassertion time is controlled by the GPMC\_CONFIG2\_i[12:8] CSRD OFFTIME field. It controls the address hold time from nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC\_CONFIG3\_i[3:0] ADV ONTIME field.
  - nADV deassertion time is controlled by the GPMC\_CONFIG3\_i[12:8] ADV RD OFFTIME field.
- Output enable signal nOE:
  - nOE assertion indicates a read cycle.
  - nOE assertion time is controlled by the GPMC\_CONFIG4\_i[3:0] OE ONTIME field.
  - nOE deassertion time is controlled by the GPMC\_CONFIG4\_i[12:8] OE OFFTIME field.
- Read data is latched when RDACCESSTIME completes. Access time is defined in the GPMC.GPMC\_CONFIG5\_i[20:16] RDACCESSTIME field.
- The end of the access is defined by the RDCYCLETIME parameter. The read cycle time is defined in the GPMC.GPMC\_CONFIG5\_i[4:0] RDCYCLETIME field.

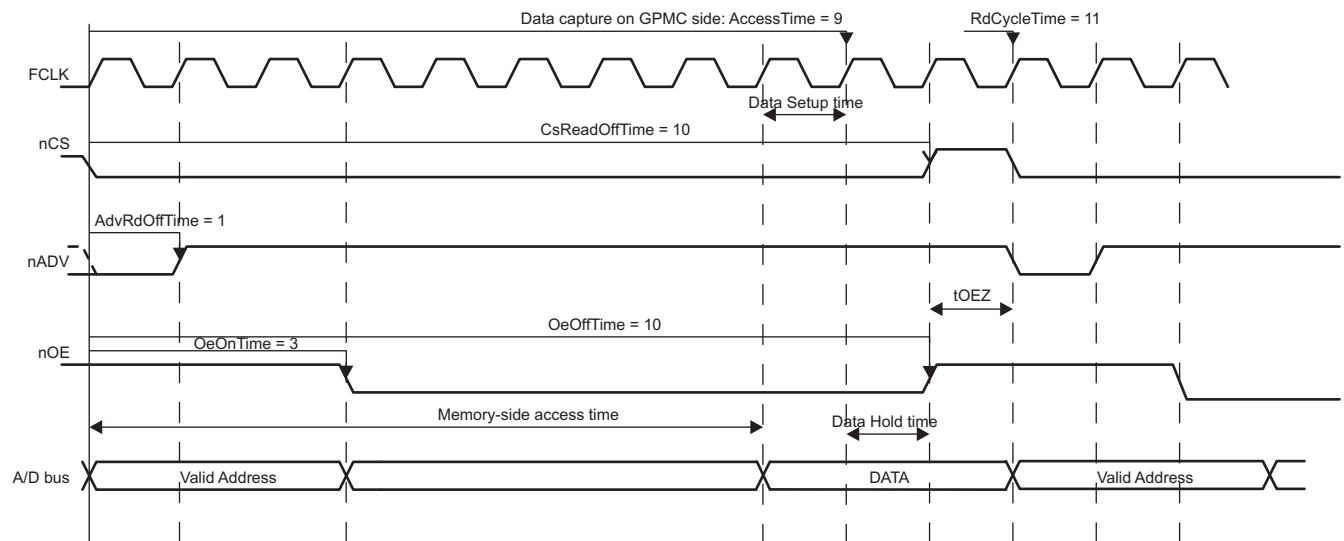

- Direction signal DIR: DIR goes from OUT to IN at the same time that nOE is asserted.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See [Section 11.1.5.3.10, Bus Keeping Support](#) for more details.

### 11.1.5.9.1.2 Asynchronous Single-Read Operation on an Address/Data Multiplexed Device

Figure 11-11 shows an asynchronous single read operation on an address/data-multiplexed device.

**Figure 11-11. Asynchronous Single Read on an Address/Data-Multiplexed Device**

gpmc-011

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For details, see [Section 11.1.5.2.3, Address/Data-Multiplexing Interface](#).

GPMC.GPMC\_CONFIG1\_i register settings (i = 0 to 7):

- READMULTIPLE bit at 0 (read single access)
- READTYPE bit at 0 (read asynchronous)
- MUXADDDATA bit at 1 (address/data-multiplexed device)

Address bits ([16:1] from a GPMC perspective, [15:0] from an external device perspective) are placed on the address/data bus, and the remaining address bits [25:16] are placed on the address bus. The address phase ends at nOE assertion, when the DIR signal goes from OUT to IN.

The nCS, nADV, nOE, and DIR signals are controlled in the same way as nonmultiplexed accesses.

### 11.1.5.9.2 Asynchronous Single Write

#### 11.1.5.9.2.1 Asynchronous Single Write Operation on a Nonmultiplexed Device

Figure 11-12 shows an asynchronous single write operation on a nonmultiplexed device.

**Figure 11-12. Asynchronous Single Write on an Address/Data-Nonmultiplexed Device**

In the following section *i* stands for the chip-select number, *i* = 0 to 7.

- GPMC.GPMC\_CONFIG[1] LIMITEDADDRESS set to 1 (A26-A11 are not modified during an external memory access)
- GPMC.GPMC\_CONFIG1\_i register settings:
  - WRITEMULTIPLE bit at 0 (write single access)
  - WRITETYPE bit at 0 (write asynchronous)
  - MUXADDDATA bit at 0 (nonaddress/data-multiplexed device)
- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC.GPMC\_CONFIG2\_i[3:0] CSONTIME field and ensures address setup time to nCS assertion.
  - nCS deassertion time is controlled by the GPMC.GPMC\_CONFIG2\_i[20:16] CSWROFFTIME field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC.GPMC\_CONFIG3\_i[3:0] ADVONTIME field.
  - nADV deassertion time is controlled by the GPMC.GPMC\_CONFIG3\_i[20:16] ADVWROFFTIME field.

Address and data are driven on their corresponding buses at start-of-cycle time.

- Write enable signal nWE:
  - nWE assertion indicates a write cycle.
  - nWE assertion time is controlled by the GPMC.GPMC\_CONFIG4\_i[19:16] WEONTIME field.
  - nWE deassertion time is controlled by the GPMC.GPMC\_CONFIG4\_i[28:24] WEOFFTIME field.
- Direction signal DIR:

DIR signal is OUT during the entire access.

- The end of the access is defined by the WRCYCLETIME parameter.

This write-cycle time is defined in the GPMC.GPMC\_CONFIG5\_i[12:8] WRCYCLETIME field.

After a write operation, if no other access (read or write) is pending, the data bus keeps its previous value. See [Section 11.1.5.3.10, Bus Keeping Support](#).

In the GPMC, when a 16-bit wide device is attached to the controller, a Word32 write access is split into two Word16 write accesses. For more information about GPMC access size and type adaptation, see [Section 11.1.5.2.7, System Burst Versus External Device Burst Support](#).

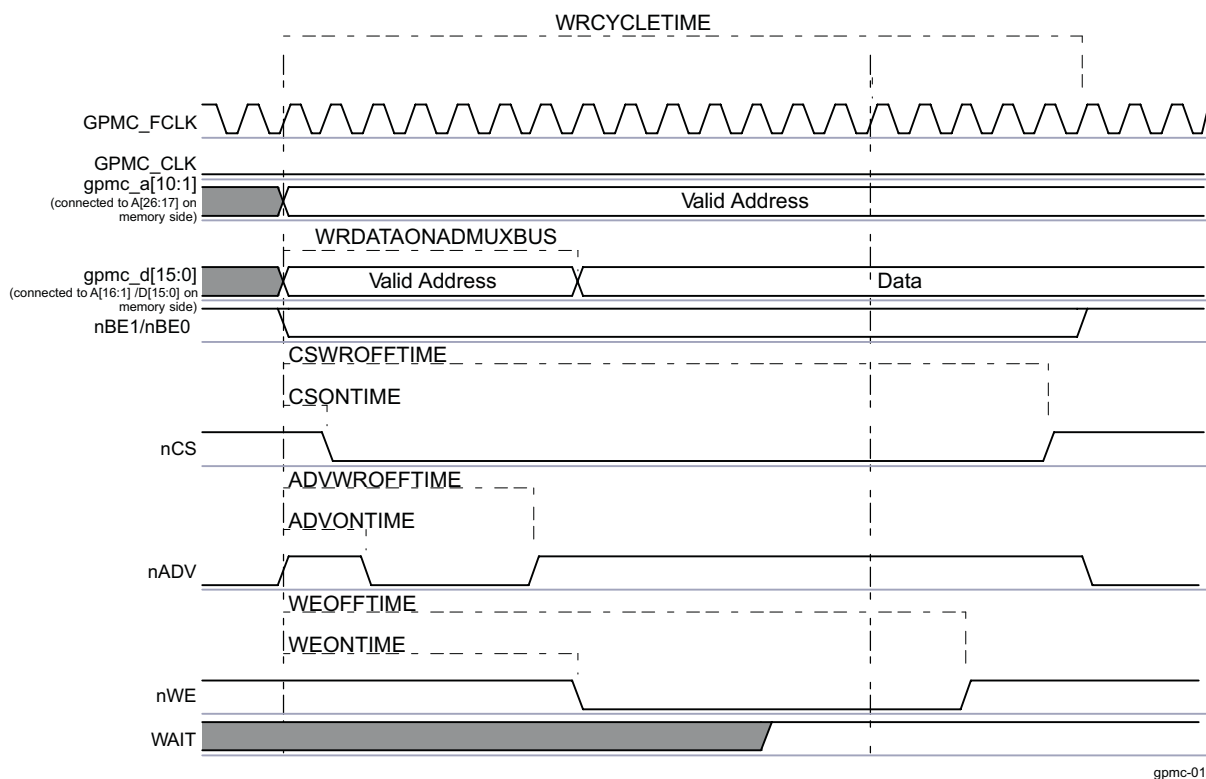

Between two successive accesses, if an nCS pulse is needed:

- The GPMC.GPMC\_CONFIG6\_i[11:8] CYCLE2CYCLEDELAY field can be programmed with GPMC.GPMC\_CONFIG6\_i[7] CYCLE2CYCLESAMECSSEN enabled.
- The CSWROFFTIME and CSQNTIME parameters also allow a chip-select pulse, but this affects all other types of access.

### 11.1.5.9.2.2 Asynchronous Single Write Operation on an Address/Data-Multiplexed Device

[Figure 11-13](#) shows an asynchronous single write operation on an address/data-multiplexed device.

**Figure 11-13. Asynchronous Single Write on an Address/Data-Multiplexed Device**

When the GPMC generates a write access to an address/data-multiplexed device, it drives the address on the address/data muxed bus until WRDATAONADMUXBUS time, and then it drives the data. For more information, see [Section 11.1.5.2.3, Address/Data-Multiplexing Interface](#).

GPMC.GPMC\_CONFIG1\_i register settings (i = 0 to 7):

- WRITEMULTIPLE bit at 0 (write single access)
- WRITETYPE bit at 0 (write asynchronous)
- MUXADDDATA bit at 1 (address/data-multiplexed device)

Address bits [16:1] are placed on the address/data bus at the start of cycle time, and the remaining address bits [26:17] are placed on the address bus.

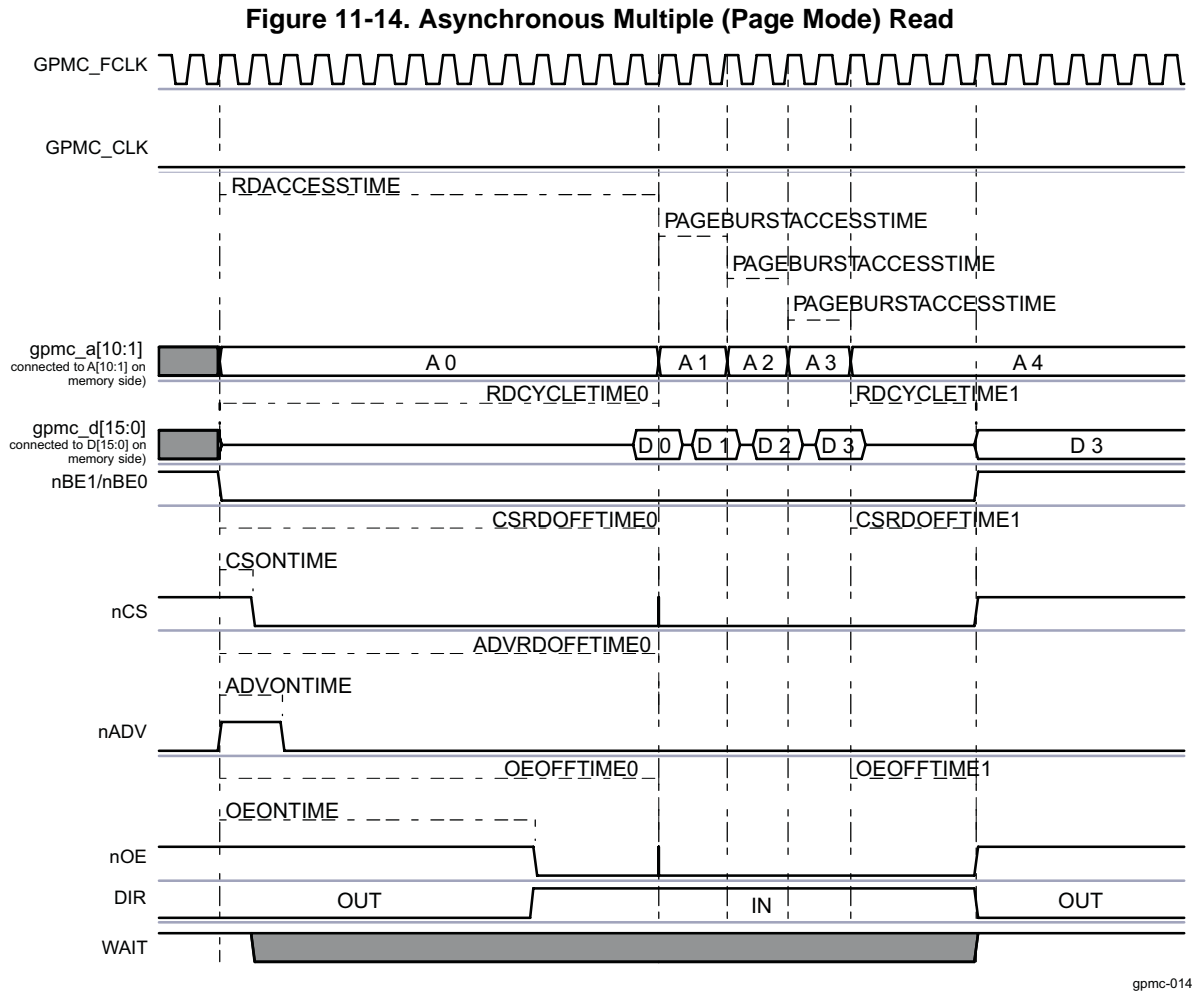

The nCS, nADV, and nWE signals are controlled in the same way as nonmultiplexed accesses.

Data is driven on the address/data bus at a [GPMC\\_CONFIG6\\_i\[19:16\]](#) WRDATAONADMUXBUS time.

**NOTE:** Write multiple access in asynchronous mode is not supported. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

### 11.1.5.9.3 Asynchronous Multiple (Page Mode) Read

Figure 11-14 shows an asynchronous multiple read operation.

**NOTE:** The WAIT signal is active low.

In the following section *i* stands for the chip-select number, *i* = 0 to 7.

For read access with [GPMC\\_CONFIG1\\_i](#) register settings:

- READMULTIPLE bit at 1 (read multiple access)
- READTYPE bit at 0 (read asynchronous)
- MUXADDDATA bit at 0 (non-address/data-multiplexed device). The page mode is not supported by address/data-multiplexed devices.

In [Figure 11-14](#), two Word32 read host accesses on the GPMC configured with `READMULTIPLE = 1`, `READYTYPE = 0`, and `MUXADDDATA = 0` are merged into one multiple-read access (page mode of four Word16) on the attached device.

When `RDACCESSTIME` completes, control-signal timings are frozen during the multiple data transactions, corresponding to `PAGEBURSTACCESSTIME` multiplied by the number of remaining data transactions.

- Chip-select signal `nCS`:
  - `nCS` assertion time is controlled by the GPMC.`GPMC_CONFIG2_i[3:0]` `CSONTIME` field and ensures the address setup time to `nCS` assertion.
  - `nCS` deassertion time is controlled by the GPMC.`GPMC_CONFIG2_i[12:8]` `CSRDOFFTIME` field and ensures the address hold time to `nCS` deassertion.
- Address valid signal `nADV`:
  - `nADV` assertion time is controlled by the GPMC.`GPMC_CONFIG3_i[3:0]` `ADVONTIME` field.
  - `nADV` deassertion time is controlled by the GPMC.`GPMC_CONFIG3_i[12:8]` `ADVRDOFFTIME` field.
- Output enable signal `nOE`:
  - `nOE` assertion indicates a read cycle.
  - `nOE` assertion time is controlled by the GPMC.`GPMC_CONFIG4_i[3:0]` `OEONTIME` field.
  - `nOE` deassertion time is controlled by the GPMC.`GPMC_CONFIG4_i[12:8]` `OEOFFTIME` field.
- Initial latency for the first read data is controlled by the `RDACCESSTIME` parameter. The access time is defined in the GPMC.`GPMC_CONFIG5_i[20:16]` `RDACCESSTIME` field.

During consecutive accesses, the GPMC increments the address after each data read completes.

- Delay between successive read data in the page is controlled by the `PAGEBURSTACCESSTIME` parameter:
  - This timing is defined in the GPMC.`GPMC_CONFIG5_i[27:24]` `PAGEBURSTACCESSTIME` field.
  - Depending on the device page length, the GPMC can control device page crossing during a burst request and insert initial `RDACCESSTIME` latency. Note that page crossing is only possible with a new burst access, meaning a new initial access phase is initiated.
- Total access time (`RDCYCLETIME`) corresponds to `RDACCESSTIME` plus the address hold time starting from the `nCS` deassertion plus the time from `RDACCESSTIME` to `CSRDOFFTIME`.
  - The read cycle time is defined in the GPMC.`GPMC_CONFIG5_i[4:0]` `RDCYCLETIME` field.
  - In [Figure 11-14](#), the `RDCYCLETIME` programmed value equals `RDCYCLETIME0` (before paged accesses) + `RDCYCLETIME1` (after paged accesses).
- Direction signal `DIR`:
  - `DIR` goes from `OUT` to `IN` at the same time as `nOE` assertion time.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See [Section 11.1.5.3.10, Bus Keeping Support](#).

### 11.1.5.10 Synchronous Access

In synchronous operations:

- The `GPMC_CLK` clock is provided outside the GPMC when accessing the memory device.
- The `GPMC_CLK` clock is derived from the `GPMC_FCLK` clock using the GPMC.`GPMC_CONFIG1_i[1:0]` `GPMCFCLKDIVIDER` field (where  $i = 0$  to 7).
- The GPMC.`GPMC_CONFIG1_i[26:25]` `CLKACTIVATIONTIME` field specifies that the `GPMC_CLK` is provided outside the GPMC 0, 1, or 2 `GPMC_FCLK` cycles after start access time until `CycleTime` completes.
- When the GPMC is configured for synchronous mode, the `GPMC_CLK` signal (which is an output) must also be set as an input (`CONTROL.CONTROL_PADCONF_GPMC_NCS7[24]` `INPUTENABLE1 = 1`). `GPMC_CLK` is looped back through the output and input buffers of the corresponding `GPMC_CLK` pad at OMAP boundary. The looped-back clock is used to synchronize the sampling of the memory signals.

11.1.5.10.1 Synchronous Single Read

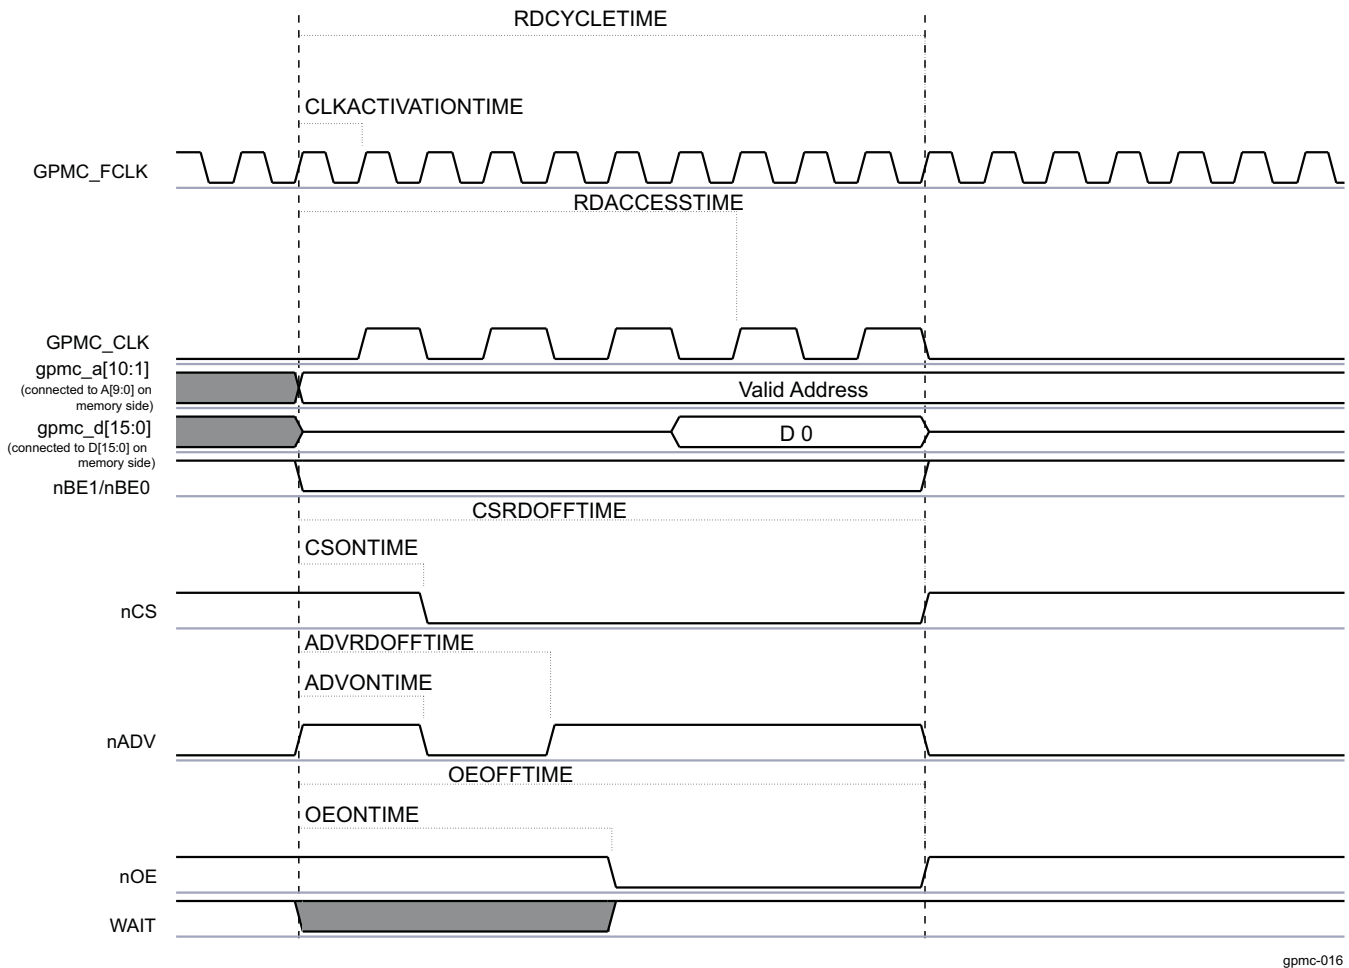

Figure 11-15 and Figure 11-16 show a synchronous single-read operation with GPMCFCLKDIVIDER equal to 0 and 1, respectively.

Figure 11-15. Synchronous Single Read (GPMCFCLKDIVIDER = 0)

gpmc-015

**Figure 11-16. Synchronous Single Read (GPMCFCLKDIVIDER = 1)**

gpmc-016

In the following section *i* stands for the chip-select number, *i* = 0 to 7.

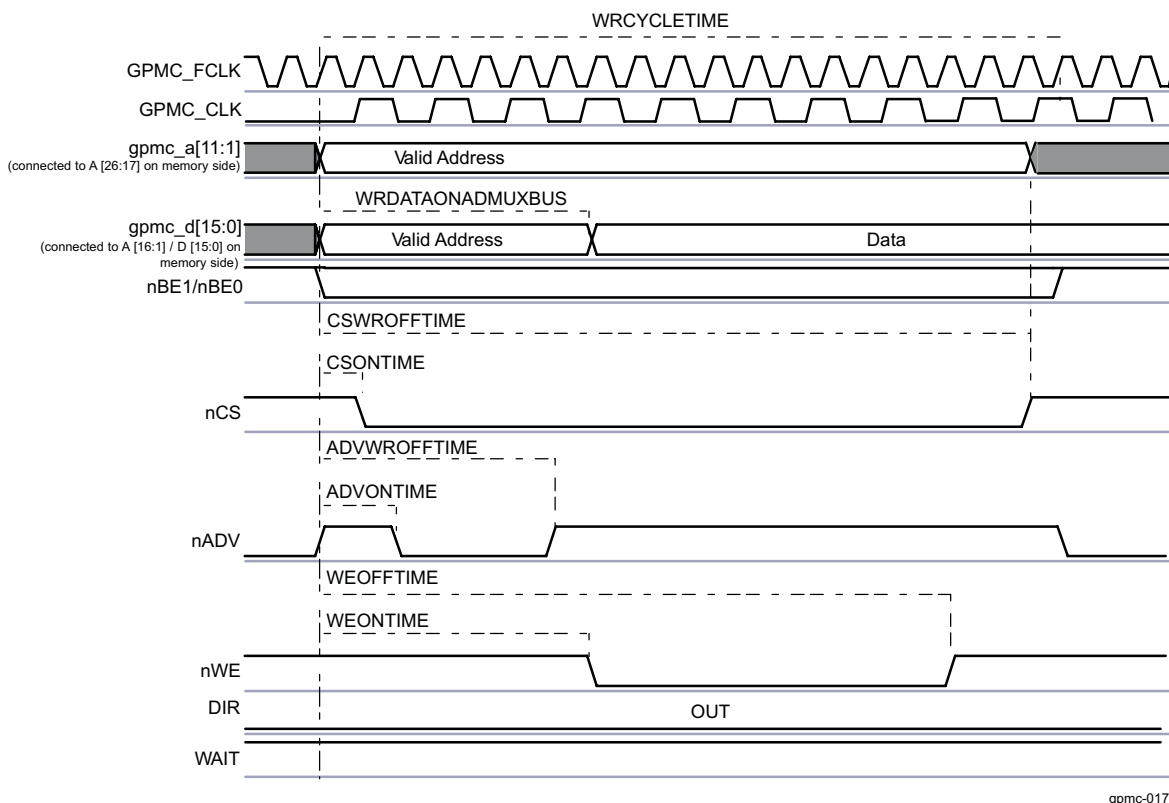

- GPMC.GPMC\_CONFIG1\_*i* register settings:
  - READMULTIPLE bit at 0 (read single access)
  - READTYPE bit at 1 (read synchronous)
  - MUXADDDATA bit at 0 (non-address/data-multiplexed device)
- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC.GPMC\_CONFIG2\_*i*[3:0] CSOFTIME field and ensures address setup time to nCS assertion.
  - nCS deassertion time is controlled by the GPMC.GPMC\_CONFIG2\_*i*[12:8] CSRDOFFTIME field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC.GPMC\_CONFIG3\_*i*[3:0] ADVONTIME field.
  - nADV deassertion time is controlled by the GPMC.GPMC\_CONFIG3\_*i*[12:8] ADVRDOFFTIME field.
- Output enable signal nOE:
  - nOE assertion indicates a read cycle.
  - nOE assertion time is controlled by the GPMC.GPMC\_CONFIG4\_*i*[3:0] OEONTIME field.
  - nOE deassertion time is controlled by the GPMC.GPMC\_CONFIG4\_*i*[12:8] OEOFFTIME field.
- Initial latency for the first read data is controlled by GPMC.GPMC\_CONFIG5\_*i*[20:16] RDACCESSTIME or by monitoring the WAIT signal.

- Total access time (GPMC.GPMC\_CONFIG5\_i[4:0] RDCYCLETIME) corresponds to RDACCESSTIME plus the address hold time from nCS deassertion, plus time from RDACCESSTIME to CSWROFFTIME.
- Direction signal DIR: DIR goes from OUT to IN at the same time as nOE assertion.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See Section 11.1.5.3.10, *Bus Keeping Support*.

### 11.1.5.10.2 Synchronous Single Write

Figure 11-17. Synchronous Single Write on an Address/Data-Multiplexed Device

**NOTE:** The WAIT signal is active low.

When the GPMC generates a write access to an address/data-multiplexed device, it drives the data bus until WRDATAONADMUXBUS time (GPMC\_CONFIG6\_i[19:16]).

The GPMC.GPMC\_CONFIG1\_i register settings (i = 0 to 7) are as follows:

- WRITEMULTIPLE bit at 0 (write single access)
- WRITETYPE bit at 1 (write synchronous)
- MUXADDDATA bit at 1 (address/data-multiplexed device)

Address bits [16:1] are placed on the address/data bus at cycle-start time, and the remaining address bits [26:17] are placed on the address bus.

The address phase ends at WRDATAONADMUXBUS.

The nCS, nADV, and nWE signals are controlled in the same way as nonmultiplexed accesses.

First data of the burst is driven on the address/data bus at WRDATAONADMUXBUS time.

11.1.5.10.3 Synchronous Multiple (Burst) Read (4-, 8-, 16-Word 16 Burst With Wraparound Capability)

Figure 11-18 and Figure 11-19 show a synchronous multiple read operation with GPMCFCLKDivider equal to 0 and 1, respectively.

Figure 11-18. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 0)

gpmc-018

**NOTE:** The WAIT signal is active low.

Figure 11-19. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 1)

NOTE: The WAIT signal is active low.

In the following section *i* stands for the chip-select number, *i* = 0 to 7.

- GPMC.GPMC\_CONFIG1\_i register settings:
  - READMULTIPLE bit at 1 (read multiple access)
  - READTYPE bit at 1 (read synchronous)
  - MUXADDDATA bit at 0 (nonaddress/data-multiplexed device)

When RDACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC.GPMC\_CONFIG2\_i[3:0] CSONTIME field and ensures address setup time to nCS assertion.
  - nCS deassertion time is controlled by the GPMC.GPMC\_CONFIG2\_i[12:8] CSRDOFFTIME field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC.GPMC\_CONFIG3\_i[3:0] ADVONTIME field.
  - nADV deassertion time is controlled by the GPMC.GPMC\_CONFIG3\_i[12:8] ADVRDOFFTIME field.
- Output enable signal nOE:
  - nOE assertion indicates a read cycle.
  - nOE assertion time is controlled by the GPMC.GPMC\_CONFIG4\_i[3:0] OEONTIME field.
  - nOE deassertion time is controlled by the GPMC.GPMC\_CONFIG4\_i[12:8] OEOFFTIME field.
- Initial latency for the first read data is controlled by GPMC.GPMC\_CONFIG5\_i[20:16] RDACCESSTIME or by monitoring the WAIT signal.
- Successive read data are provided by the memory device each one or two GPMC\_CLK cycles. The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMCFCLKDIVIDER and the

memory-device internal configuration.

Depending on the device page length, the GPMC can control device page crossing during a new burst request and purposely insert initial latency.

- Total access time (RDCYCLETIME) corresponds to RDACCESSTIME plus the address hold time from nCS deassertion, plus the time from RDACCESSTIME to CSRDOFFTIME.
  - RDCYCLETIME is defined in the GPMC.GPMC\_CONFIG5\_i register.
  - In [Figure 11-19](#), the RDCYCLETIME programmed value equals RDCYCLETIME0 + RDCYCLETIME1.
- Direction signal DIR:
  - DIR goes from OUT to IN at the same time as nOE assertion.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See [Section 11.1.5.3.10](#), *Bus Keeping Support*.

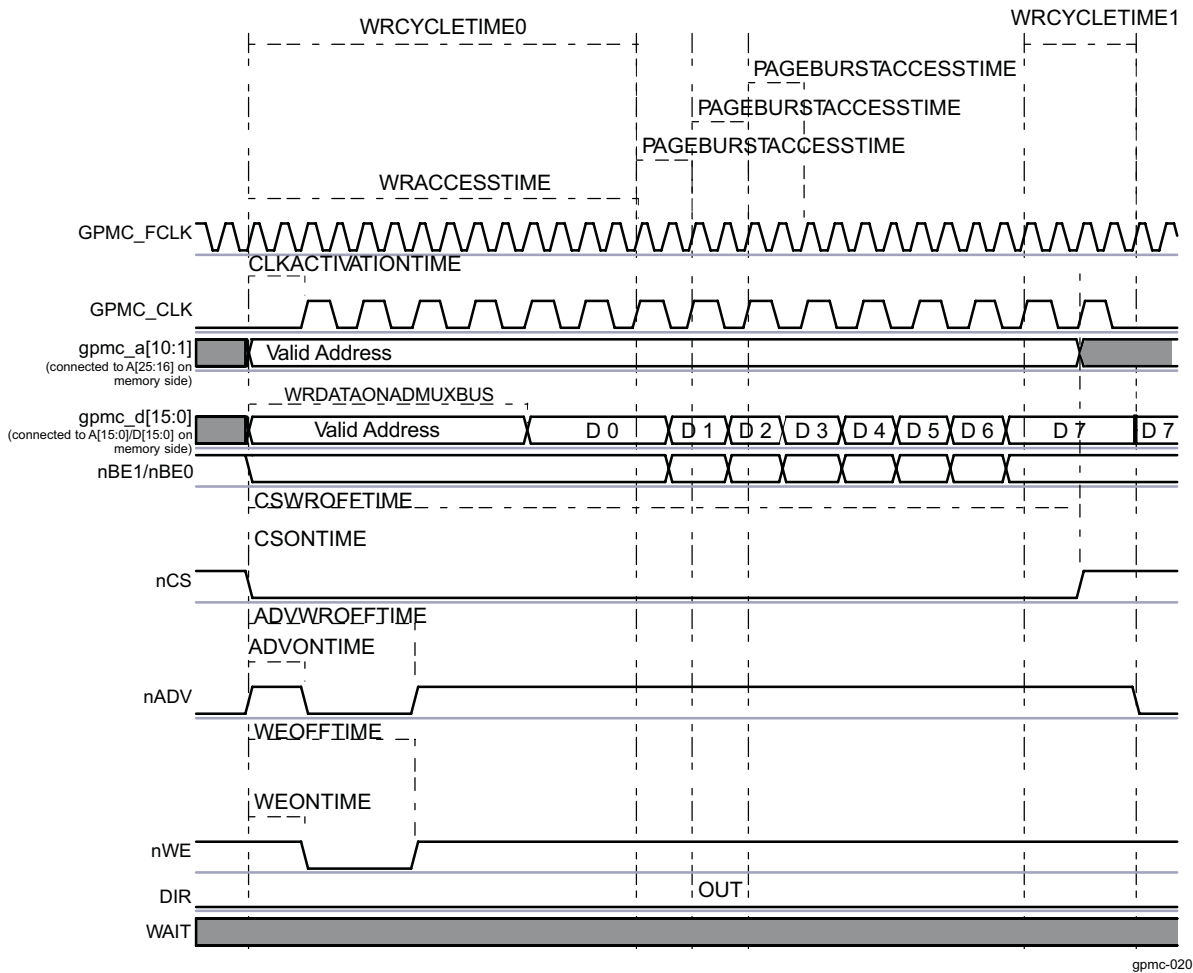

- Burst wraparound
  - The GPMC.GPMC\_CONFIG1\_i[31] WRAPBURST bit allows a 4-, 8-, or 16-Word16 linear burst access to wrap within its burst-length boundary.

#### 11.1.5.10.4 Synchronous Multiple (Burst) Write

Burst write mode provides synchronous single or consecutive accesses.

[Figure 11-20](#) shows a synchronous multiple (burst) write.

Figure 11-20. Synchronous Multiple (Burst) Write

NOTE: The WAIT signal is active low.

In the following section *i* stands for the chip-select number, *i* = 0 to 7.

- GPMC.GPMC\_CONFIG1\_*i* register settings:
  - WRITEMULTIPLE bit at 1 (write multiple access)
  - WRITETYPE bit at 1 (write synchronous)
  - MUXADDDATA bit at 1 (address/data-multiplexed device)

When WRACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to the PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC.GPMC\_CONFIG2\_*i*[3:0] CSONTIME field and ensures address setup time to nCS assertion.
  - nCS deassertion time controlled by the GPMC.GPMC\_CONFIG2\_*i*[20:16] CSWROFFTIME field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC.GPMC\_CONFIG3\_*i*[3:0] ADVONTIME field.
  - nADV deassertion time is controlled by the GPMC.GPMC\_CONFIG3\_*i*[20:16] ADVWROFFTIME field.
- Write enable signal nWE:

- nWE assertion indicates a write cycle.
- nWE assertion time is controlled by the GPMC.GPMC\_CONFIG4\_i[19:16] WEONTIME field.
- nWE deassertion time is controlled by the GPMC.GPMC\_CONFIG4\_i[28:24] WEOFFTIME field.

---

**NOTE:** The nWE falling edge must not be used to control the time when the burst first data is driven in the address / data bus because some new devices require the nWE signal at low during the address phase.

---

- First write data is driven by the GPMC at WRDATAONADMUXBUS (GPMC\_CONFIG6\_i[19:16]), when in address/data mux configuration. The next write data of the burst is driven on the bus at WRACCESSTIME + 1 during PAGEBURSTACCESSTIME GPMC\_FCLK cycles. The last data of the synchronous burst write is driven until WRCYCLETIME completes.
  - WRACCESSTIME is defined in the GPMC.GPMC\_CONFIG5\_i register.
  - The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMCFCLKDIVIDER and the memory-device internal configuration.
- Total access time (WRCYCLETIME) corresponds to WRACCESSTIME plus the address hold time from nCS deassertion, plus time from WRACCESSTIME to CSWROFFTIME.
  - WRCYCLETIME is defined in the GPMC.GPMC\_CONFIG5\_i register.
  - In [Figure 11-20](#), the WRCYCLETIME programmed value equals WRCYCLETIME0 + WRCYCLETIME1.
- Direction signal DIR:
  - DIR is OUT during the entire access.

After a write operation, if no other access (read or write) is pending, the data bus keeps the previous value. See [Section 11.1.5.3.10, Bus Keeping Support](#).

[Figure 11-21](#) shows the same synchronous burst write access when the chip-select is configured in address/data-multiplexed mode.

**Figure 11-21. Synchronous Multiple Write (Burst Write) in Address/Data-Multiplexed Mode**

The first data of the burst is driven on the a/d bus at [GPMC\\_CONFIG6\\_i\[19:16\]](#) WRDATAONADMUXBUS.

### 11.1.5.11 pSRAM Basic Programming Model

pSRAM devices are SRAM-pin-compatible low-power memories that contain a self-refreshed DRAM memory array. These devices can be accessed by the GPMC with the [GPMC.GPMC\\_CONFIG1\\_i\[11:10\]](#) DEVICETYPE field (i = 0 to 7).

The pSRAM devices support the following operations:

- Asynchronous single read
- Asynchronous page read
- Asynchronous single write
- Synchronous single read and write
- Synchronous burst read
- Synchronous burst write

pSRAM devices must be powered up and initialized in a predefined manner according to the specifications of the attached device.

pSRAM devices can be programmed to use either mode: fixed or variable latency. pSRAM devices can either automatically schedule autorefresh operations, which force the GPMC to use its WAIT signal capability when read or write operations occur during an internal self-refresh operation, or pSRAM devices automatically include the autorefresh operation in the access time. These devices do not require additional WAIT signal capability or a minimum nCS high pulse width between consecutive accesses to ensure that the correct internal refresh operation is scheduled.

In both pSRAM cases, the GPMC configuration for this chip-select must be set according to the specifications of the attached device.

### 11.1.5.12 Error Handling

When an error occurs in the GPMC, the error information is stored in the GPMC.GPMC\_ERR\_TYPE register and the address of the illegal access is stored in the GPMC.GPMC\_ERR\_ADDRESS register. The GPMC only keeps the first error abort information until the GPMC.GPMC\_ERR\_TYPE register is reset. Subsequent accesses that cause errors are not logged until the error is cleared by hardware with the GPMC.GPMC\_ERR\_TYPE[0] ERRORVALID bit.

- ERRORNOTSUPPADD occurs when an incoming system request address decoding does not match any valid chip-select region, or if two chip-select regions are defined as overlapped, or if a register file access is tried outside the valid address range of 1 Kbyte.
- ERRORNOTSUPPMCMD occurs when an unsupported command request is decoded at the L3 interconnect interface.
- ERRORTIMEOUT: A time-out mechanism prevents the system from hanging. The start value of the 9-bit time-out counter is defined in the GPMC.GPMC\_TIMEOUT\_CONTROL register and enabled with the GPMC.GPMC\_TIMEOUT\_CONTROL[0] TIMEOUTENABLE bit. When enabled, the counter starts at start-cycle time until it reaches 0 and data is not responded to from memory, then a time-out error occurs. When data are sent from memory, this counter is reset to its start value. With multiple accesses (asynchronous page mode or synchronous burst mode), the counter is reset to its start value for each data access within the burst.

The GPMC does not generate interrupts on these errors. True abort to the MPU or interrupt generation is handled at interconnect level.

### 11.1.5.13 Boot Configuration

See [Section 11.1.3.3.2](#), *GPMC CS0 Default Configuration at IC Reset*.

### 11.1.5.14 NAND Device Basic Programming Model

NAND (8-bit and 16-bit) memory devices using a classical NAND asynchronous address/data-multiplexing scheme can be supported on any chip-select with the appropriate asynchronous configuration settings.

As for any other type of memory compatible with the GPMC interface, accesses to a chip-select allocated to a NAND device can be interleaved with accesses to chip-selects allocated to other external devices. This interleaved capability limits the system to chip enable dont care NAND devices since the chip-select allocated to the NAND device has to be de-asserted if accesses to other chip-selects are requested.

#### 11.1.5.14.1 NAND Memory Device in Byte or Word16 Stream Mode

NAND devices require correct command and address programming before data array read or write accesses. The GPMC does not include specific hardware to translate a random address system request into a NAND-specific multiphase access. In that sense, GPMC NAND support, as opposed to random memory-map device support, is data-stream-oriented (byte or Word16).

The GPMC NAND programming model relies on a software driver for address and command formatting with the correct data address pointer value according to the block and page structure. Because of NAND structure and protocol interface diversity, the GPMC does not support automatic command and address phase programming, and software drivers must access the NAND device ID to ensure that correct command and address formatting are used for the identified device.

NAND device data read and write accesses are achieved through an asynchronous read or write access. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Any chip-select region can be qualified as a NAND region to constrain the nADV/ALE signal as Address Latch Enable (ALE active high, default state value at low) during address program access, and the nBE0/CLE signal as Command Latch Enable (CLE active high, default state value at low) during command program access. GPMC address lines are not used (the previous value is not changed) during NAND access.

### 11.1.5.14.1.1 Chip-Select Configuration for NAND Interfacing in Byte or Word Stream Mode

The GPMC.GPMC\_CONFIG7\_i register (where i = 0 to 7) associated with a NAND device region interfaced in byte or word stream mode can be initialized with a minimum size of 16 Mbytes, because any address location in the chip-select memory region can be used to access a NAND data array. The NAND Flash protocol specifies an address sequence where address bits are passed through the data bus in a series of write accesses with the ALE pin asserted. After this address phase, all operations are streamed and the system requests address is irrelevant.

#### CAUTION

To allow correct command, address, and data-access controls, the GPMC.GPMC\_CONFIG1\_i register associated with a NAND device region must be initialized in asynchronous read and write modes with the parameters listed in Table 11-4. Failure to comply with these settings corrupts the NAND interface protocol.

**Table 11-4. Chip-Select Configuration for NAND Interfacing**

Bit Field	Register	Value	Comments
WRAPBURST	GPMC_CONFIG1_i[31] <sup>(1)</sup>	0	No wrap
READMULTIPLE	GPMC_CONFIG1_i[30]	0	Single access
READTYPE	GPMC_CONFIG1_i[29]	0	Asynchronous mode
WRITEMULTIPLE	GPMC_CONFIG1_i[28]	0	Single access
WRITETYPE	GPMC_CONFIG1_i[27]	0	Asynchronous mode
CLKACTIVATIONTIME	GPMC_CONFIG1_i[26:25]	00	
ATTACHEDDEVICEPAGELENGTH	GPMC_CONFIG1_i[24:23]	Don't care	Single-access mode
WAITREADMONITORING	GPMC_CONFIG1_i[22]	0	Wait not monitored by GPMC access engine
WAITWRITEMONITORING	GPMC_CONFIG1_i[21]	0	Wait not monitored by GPMC access engine
WAITMONITORINGTIME	GPMC_CONFIG1_i[19:18]	Don't care	Wait not monitored by GPMC access engine
WAITPINSELECT	GPMC_CONFIG1_i[17:16]		Select which wait is monitored by edge detectors
DEVICESIZE	GPMC_CONFIG1_i[13:12]	0b00 or 0b01	8- or 16-bit interface
DEVICETYPE	GPMC_CONFIG1_i[11:10]	0b10	NAND device in stream mode
MUXADDDATA	GPMC_CONFIG1_i[9]	0	Nonmultiplexed mode
TIMEPARAGRANULARITY	GPMC_CONFIG1_i[4]	0	Timing achieved with best GPMC clock granularity
GPMCCLKDIVIDER	GPMC_CONFIG1_i[1:0]	Don't care	Asynchronous mode

<sup>(1)</sup> i = 0 to 7

The GPMC.GPMC\_CONFIG1\_i to GPMC.GPMC\_CONFIG4\_i register (where i = 0 to 7) associated with a NAND device region must be initialized with the correct control-signal timing value according to the NAND device timing parameters.

### 11.1.5.14.1.2 NAND Device Command and Address Phase Control

NAND devices require multiple address programming phases. The CPU software driver is responsible for issuing the correct number of command and address program accesses, according to the device command set and the device address-mapping scheme.

NAND device-command and address-phase programming is achieved through write requests to the GPMC.GPMC\_NAND\_COMMAND\_i and GPMC.GPMC\_NAND\_ADDRESS\_i register locations (i = 0 to 7) with the correct command and address values. These locations are mapped in the associated chip-select register region. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Command and address values are not latched during the access and cannot be read back at the register location.

- Only write accesses must be issued to these locations, but the GPMC does not discard any read access. Accessing a NAND device with nOE and CLE or ALE asserted (read access) can produce undefined results.
- Write accesses to the GPMC.GPMC\_NAND\_COMMAND\_i register location and to the GPMC.GPMC\_NAND\_ADDRESS\_i register location must be posted for faster operations (i = 0 to 7). The GPMC.GPMC\_CONFIG[0] NANDFORCEPOSTEDWRITE bit enables write accesses to these locations as posted, even if they are defined as nonposted.

A write buffer is used to store write transaction information before the external device is accessed:

- Up to eight consecutive posted write accesses can be accepted and stored in the write buffer.
- For nonposted write, the pipeline is one deep.
- An GPMC.GPMC\_STATUS[0] EMPTYWRITEBUFFERSTATUS bit stores the empty status of the write buffer.

GPMC.GPMC\_NAND\_COMMAND\_i and GPMC.GPMC\_NAND\_ADDRESS\_i (i = 0 to 7) are Word32 locations, which means any Word32 or Word16 access is split into 4- or 2-byte accesses if an 8-bit wide NAND device is attached. For multiple-command phase or multiple-address phase, the software driver can use Word32 or Word16 access to these registers, but it must account for the splitting and little-endian ordering scheme. When only one byte command or address phase is required, only byte write access to GPMC.GPMC\_NAND\_COMMAND\_i and GPMC.GPMC\_NAND\_ADDRESS\_i can be used, and any of the four byte locations of the registers are valid.

The same applies to a GPMC.GPMC\_NAND\_COMMAND\_i and a GPMC.GPMC\_NAND\_ADDRESS\_i (i = 0 to 7) Word32 write access to a 16-bit wide NAND device (split into two Word16 accesses). In the case of a Word16 write access, the MSByte of the Word16 value must be set according to the NAND device requirement (usually 0). Either Word16 location or any one of the four byte locations of the registers is valid.

#### 11.1.5.14.1.3 Command Latch Cycle

Writing data at the GPMC.GPMC\_NAND\_COMMAND\_i location (i = 0 to 7) places the data as the NAND command value on the bus, using a regular asynchronous write access.

- nCE is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- CLE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE and nRE (nOE) are maintained inactive.

Figure 11-22 shows the NAND command latch cycle.

Figure 11-22. NAND Command Latch Cycle

**NOTE:** CLE is shared with the nBE0 output signal and has an inverted polarity from BE0. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, nBE0 (also nBE1) must not toggle, because it is shared with CLE.

NAND flash memories do not use byte enable signals.

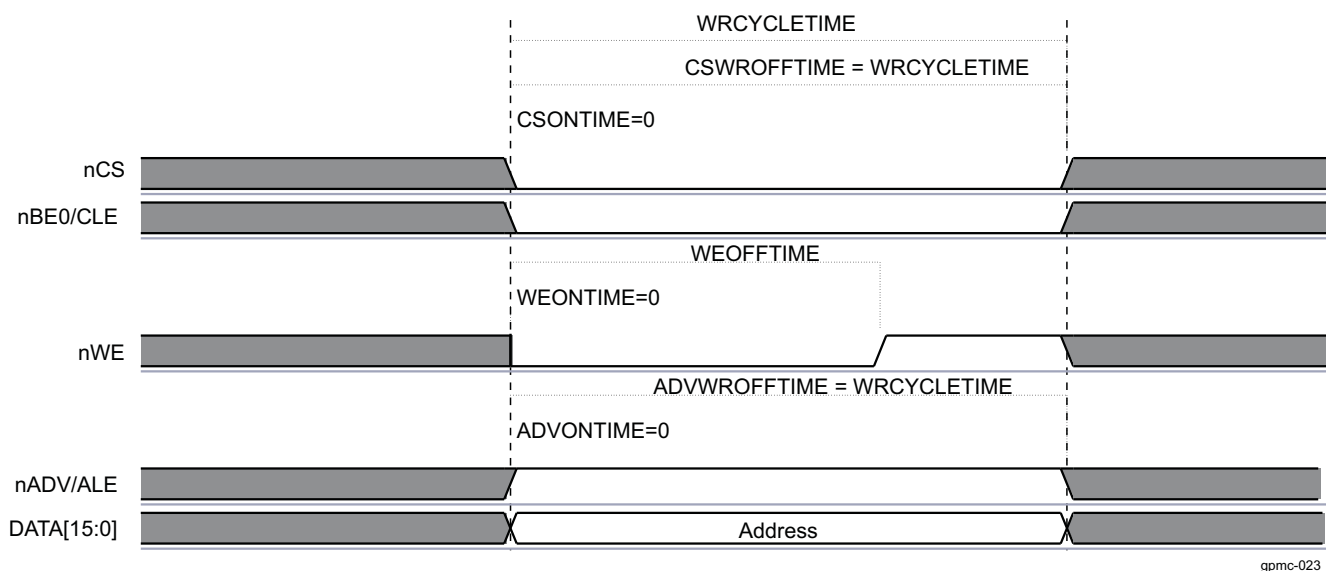

#### 11.1.5.14.1.4 Address Latch Cycle

Writing data at the GPMC.GPMC\_NAND\_ADDRESS\_i location (i = 0 to 7) places the data as the NAND partial address value on the bus, using a regular asynchronous write access.

- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- ALE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- CLE and nRE (nOE) are maintained inactive.

Figure 11-23 shows the NAND address latch cycle.

Figure 11-23. NAND Address Latch Cycle

**NOTE:** ALE is shared with the nADV output signal and has an inverted polarity from ADV. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, ALE is kept stable.

#### 11.1.5.14.1.5 NAND Device Data Read and Write Phase Control in Stream Mode

NAND device data read and write accesses are achieved through a read or write request to the chip-select-associated memory region at any address location in the region or through a read or write request to the GPMC.GPMC\_NAND\_DATA\_i location (i = 0 to 7) mapped in the chip-select-associated control register region. GPMC.GPMC\_NAND\_DATA\_i is not a true register, but an address location to enable nRE or nWE signal control. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Reading data from the GPMC.GPMC\_NAND\_DATA\_i location or from any location in the associated chip-select memory region activates an asynchronous read access.

- nCS is controlled by the CSONTIME and CSRDOFFTIME timing parameters.
- nRE is controlled by the OEONTIME and OEOFFTIME timing parameters.
- To take advantage of nRE high-to-data invalid minimum timing value, the RDACCESSTIME can be set so that data are effectively captured after nRE deassertion. This allows optimization of NAND read access cycle time completion. For optimal timing parameter settings, see the NAND device and OMAP IC timing parameters.

ALE, CLE, and nWE are maintained inactive.

Figure 11-24 shows the NAND data read cycle.

**Figure 11-24. NAND Data Read Cycle**

gpmc-024

Writing data to the GPMC.GPMC\_NAND\_DATA\_i location or to any location in the associated chip-select memory region activates an asynchronous write access.

- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE, CLE, and nRE (nOE) are maintained inactive.

Figure 11-25 shows the NAND data write cycle.

Figure 11-25. NAND Data Write Cycle

gpmc-025

#### 11.1.5.14.1.6 NAND Device General Chip-Select Timing Control Requirement

For most NAND devices, read data access time is dominated by nCS-to-data-valid timing and has faster nRE-to-data-valid timing. Successive accesses with nCS deassertions between accesses are affected by this timing constraint. Because accesses to a NAND device can be interleaved with other chip-select accesses, there is no certainty that nCS always stays low between two accesses to the same chip-select. Moreover, an nCS deassertion time between the same chip-select NAND accesses is likely to be required as follows: the nCS deassertion requires programming CYCLETIME and RDACCESSTIME according to the nCS-to-data-valid critical timing.

To get full performance from NAND read and write accesses, the prefetch engine can dynamically reduce RDCYCLETIME, WRCYCLETIME, RDACCESSTIME, WRACCESSTIME, CSRDOFFTIME, CSWROFFTIME, ADVRDOFFTIME, ADVWROFFTIME, OEOFFTIME, and WEOFFTIME on back-to-back NAND accesses (to the same memory) and suppress the minimum nCS high pulse width between accesses. For more information about optimal prefetch engine access, see [Section 11.1.5.14.4, Prefetch and Write-Posting Engine](#).

Some NAND devices require minimum write-to-read idle time, especially for device-status read accesses following status-read command programming (write access). If such write-to-read transactions are used, a minimum nCS high pulse width must be set. For this, CYCLE2CYCLESAMECSSEN and CYCLE2CYCLEDELAY must be set according to the appropriate timing requirement to prevent any timing violation.

NAND devices usually have an important nRE high to data bus in tristate mode. This requires a bus turnaround setting (BUSTURNAROUND = 1) so that the next access to a different chip-select is delayed until the BUSTURNAROUND delay completes. Back-to-back NAND read accesses to the same NAND flash are not affected by the programmed bus turnaround delay.

#### 11.1.5.14.1.7 Read and Write Access Size Adaptation

##### 11.1.5.14.1.7.1 8-Bit Wide NAND Device

Host Word16 and Word32 read and write access requests to a chip-select associated with an 8-bit wide NAND device are split into successive read and write byte accesses to the NAND memory device. Byte access is ordered according to little-endian organization. A NAND 8-bit wide device must be interfaced on the D0D7 interface bus lane. GPMC data accesses are justified on this bus lane when the chip-select is associated with an 8-bit wide NAND device.

##### 11.1.5.14.1.7.2 16-Bit Wide NAND Device

Host Word32 read and write access requests to a chip-select associated with a 16-bit wide NAND device are split into successive read and write Word16 accesses to the NAND memory device. Word16 access is ordered according to little-endian organization.

Host byte read and write access requests to a 16-bit wide NAND device are completed as 16-bit accesses on the device itself, because there is no byte-addressing capability on 16-bit wide NAND devices. This means that the NAND device address pointer is incremented on a Word16 basis and not on a byte basis. For a read access, only the requested byte is given back to the host, but the remaining byte is not stored or saved by the GPMC, and the next byte or Word16 read access gets the next Word16 NAND location. For a write access, the invalid byte part of the Word16 is driven to FF, and the next byte or Word16 write access programs the next Word16 NAND location.

Generally, byte access to a 16-bit wide NAND device should be avoided, especially when ECC calculation is enabled. 8-bit or 16-bit ECC-based computations are corrupted by a byte read to a 16-bit wide NAND device, because the nonrequested byte is considered invalid on a read access (not captured on the external data bus; FF is fed to the ECC engine) and is set to FF on a write access.

Host requests (read/write) issued in the chip-select memory region are translated in successive single or split accesses (read/write) to the attached device. Therefore, incrementing 32-bit burst requests are translated in multiple 32-bit sequential accesses following the access adaptation of the 32-bit to 8- or 16-bit device.

#### 11.1.5.14.2 NAND Device-Ready Pin

The NAND memory device provides a ready pin to indicate data availability after a block/page opening and to indicate that data programming is complete. The ready pin can be connected to one of the four WAIT GPMC input pins; data read accesses must not be tried when the ready pin is sampled inactive (device is not ready) even if the associated chip-select WAITREADMONITORING bit field is set. The duration of the NAND device busy state after the block/page opening is so long (up to 50  $\mu$ s) that accesses occurring when the ready pin is sampled inactive can stall GPMC access and eventually cause a system time-out.

---

**NOTE:** If a read access to a NAND flash is done using the wait monitoring mode, the device is blocked during a page opening, and so is the GPMC. If the correct settings are used, other chip-selects can be used while the memory processes the page opening command.

To avoid a time-out caused by a block/page opening delay in NAND flash, disable the wait pin monitoring for read and write accesses (that is, set the GPMC.GPMC\_CONFIG1\_i[21] WAITWRITEMONITORING and GPMC.GPMC\_CONFIG1\_i[22] WAITREADMONITORING bits to 0, where  $i = 0$  to 7), and use one of the following methods instead:

- Use software to poll the WAITnSTATUS bit ( $n = 0$  to 3) of the [GPMC\\_STATUS](#) register.
- Configure an interrupt that is generated on the WAIT signal change (through the GPMC.GPMC\_IRQENABLE register bits[11:8]).

Even if the READWAITMONITORING bit is not set, the external memory nR/B pin status is captured in the programmed WAIT bit in the [GPMC\\_STATUS](#) register.

The READWAITMONITORING bit method must be used for memories other than NAND flash, if they require the use of a WAIT signal.

---

##### 11.1.5.14.2.1 Ready Pin Monitored by Software Polling

The ready signal state can be monitored through the GPMC.GPMC\_STATUS WAITxSTATUS bit ( $x = 0$  to 3). The software must monitor the ready pin only when the signal is declared valid. See the NAND device timing parameters to set the correct software temporization to monitor ready only after the invalid window is complete from the last read command written to the NAND device.

##### 11.1.5.14.2.2 Ready Pin Monitored by Hardware Interrupt

Each gpmc\_wait input pin can generate an interrupt when a wait-to-no-wait transition is detected. Depending on whether the GPMC.GPMC\_CONFIG WAITxPINPOLARITY bits ( $x = 0$  to 3) is active low or active high, the wait-to-no-wait transition is a low-to-high external WAIT signal transition or a high-to-low external WAIT signal transition, respectively.

The wait transition pin detector must be cleared before any transition detection. This is done by writing 1 to the WAITxEDGEDETECTIONSTATUS bit ( $x = 0$  to 3) of the GPMC.GPMC\_IRQSTATUS register according to the gpmc\_wait pin used for the NAND device-ready signal monitoring. To detect a wait-to-no-wait transition, the transition detector requires a wait active time detection of a minimum of two GPMC\_FCLK cycles. Software must incorporate precautions to clear the wait transition pin detector before wait (busy) time completes.

A wait-to-no-wait transition detection can issue a GPMC interrupt if the WAITxEDGEDETECTIONENABLE bit in the GPMC.GPMC\_IRQENABLE register is set and if the WAITxEDGEDETECTIONSTATUS bit field in the GPMC.GPMC\_IRQSTATUS register is set.

The WAITMONITORINGTIME field does not affect wait-to-no-wait transition time detection.

It is also possible to poll the WAITxEDGEDETECTIONSTATUS bit field in the GPMC.GPMC\_IRQSTATUS register according to the gpmc\_wait pin used for the NAND device ready signal monitoring.

### 11.1.5.14.3 ECC Calculator

The general-purpose memory controller includes an error code correction (ECC) calculator circuitry that enables on-the-fly ECC calculation during data read or data program (that is, write) operations.

The user can choose from two different algorithms with different error correction capabilities: Hamming code (for 1-bit error code correction), and BCH code (for 4- or 8-bit error correction) through the GPMC\_ECC\_CONFIG[16] ECCALGORITHM bit. Only one ECC context can be active at any given time through the GPMC\_ECC\_CONFIG[3:1] ECCCS bit. Even if two CSs use different ECC algorithms, one the Hamming code and the other a BCH code, they must define separate ECC contexts, because some of the ECC registers are common to all types of algorithms.

#### 11.1.5.14.3.1 Hamming Code

All references to ECC in this section refer to the 1-bit error correction Hamming code.

The ECC is based on a two-dimensional (row and column) bit parity accumulation known as Hamming code. The parity accumulation is done for a programmed number of bytes or Word16 read from the memory device or written to the memory device in stream mode.

There is no automatic error detection or correction, and it is the software NAND driver responsibility to read the multiple ECC calculation results, compare them to the expected code value, and take the appropriate corrective actions according to the error handling strategy (ECC storage in spare byte, error correction on read, block invalidation).

The ECC engine includes a single accumulation context. It can be allocated to a single designated chip-select at a time and parallel computations on different chip-selects are not possible. Since it is allocated to a single chip-select, the ECC computation is not affected by interleaved GPMC accesses to other chip-selects and devices. The ECC accumulation is sequentially processed in the order of data read from or written to the memory on the designated chip-select. The ECC engine does not differentiate read accesses from write accesses and does not differentiate data from command or status information. It is the software responsibility to make sure only relevant data are passed to the NAND flash memory while the ECC computation engine is active.

The starting NAND page location must be programmed first, followed by an ECC accumulation context reset with an ECC enabling, if required. The NAND device accesses discussed in the following sections must be limited to data read or write until the specified number of ECC calculations is completed.

#### 11.1.5.14.3.1.1 ECC Result Register and ECC Computation Accumulation Size

The GPMC includes up to nine ECC result registers (GPMC.GPMC\_ECCj\_RESULT,  $j = 1$  to 9) to store ECC computation results when the specified number of bytes or Word16s has been computed.

The ECC result registers are used sequentially; one ECC result is stored in one ECC result register on the list, the next ECC result is stored in the next ECC result register on the list, and so forth, until the last ECC computation. The GPMC.GPMC\_ECCj\_RESULT register value is valid only when the programmed number of bytes or Word16s has been accumulated, which means that the same number of bytes or Word16s has been read from or written to the NAND device in sequence.

The GPMC.GPMC\_ECC\_CONTROL[3:0] ECCPOINTER field must be set to the correct value to select the ECC result register to be used first in the list for the incoming ECC computation process. The ECCPointer can be read to determine which ECC register is used in the next ECC result storage for the ongoing ECC computation. The GPMC.GPMC\_ECCj\_RESULT register value (j = 1 to 9) can be considered valid when ECCPOINTER equals j + 1. When GPMC.GPMC\_ECCj\_RESULT (where j = 9) is updated, ECCPOINTER is frozen at 10, and ECC computing is stopped (ECCENABLE = 0).

The ECC accumulator must be reset before any ECC computation accumulation process. The GPMC.GPMC\_ECC\_CONTROL[8] ECCCLEAR bit must be set to 1 (nonpersistent bit) to clear the accumulator and all ECC result registers.

For each ECC result (each GPMC.GPMC\_ECCj\_RESULT register, j = 1 to 9), the number of bytes or Word16s used for ECC computing accumulation can be selected from between two programmable values.

The ECCjRESULTSIZES bits (j = 1 to 9) in the GPMC.GPMC\_ECC\_SIZE\_CONFIG register select which programmable size value (ECCSIZE0 or ECCSIZE1) must be used for this ECC result (stored in GPMC.GPMC\_ECCj\_RESULT).

The ECCSIZE0 and ECCSIZE1 fields allow selection of the number of bytes or Word16s used for ECC computation accumulation. Any even values from 2 to 512 are allowed.

Flexibility in the number of ECCs computed and the number of bytes or Word16s used in the successive ECC computations enables different NAND page error-correction strategies. Usually based on 256 or 512 bytes and on 128 or 256 Word16, the number of ECC results required is a function of the NAND device page size. Specific ECC accumulation size can be used when computing the ECC on the NAND spare byte.

For example, with a 2-Kbyte data page 8-bit-wide NAND device, eight ECCs accumulated on 256 bytes can be computed and added to one extra ECC computed on the 24 spare bytes area where the eight ECC results used for comparison and correction with the computed data page ECC are stored. The GPMC then provides nine GPMC.GPMC\_ECCj\_RESULT registers (j = 1 to 9) to store the results. In this case, ECCSIZE0 is set to 256, and ECCSIZE1 is set to 24; the ECC[1:8]RESULTSIZES bits are set to 0, and the ECC9RESULTSIZES bit is set to 1.

#### 11.1.5.14.3.1.2 ECC Enabling

The GPMC.GPMC\_ECC\_CONFIG[3:0] ECCCS field selects the allocated chip-select. The GPMC.GPMC\_ECC\_CONFIG[0] ECCENABLE bit enables ECC computation on the next detected read or write access to the selected chip-select.

The ECCPOINTER, ECCCLEAR, ECCSIZE, ECCjRESULTSIZES (where j = 1 to 9), ECC16B, and ECCCS fields must not be changed or cleared while an ECC computation is in progress.

The ECC accumulator and ECC result register must not be changed or cleared while an ECC computation is in progress.

Table 11-5 describes the ECC enable settings.

**Table 11-5. ECC Enable Settings**

Bit Field	Register	Value	Comments
ECCCS	GPMC_ECC_CONFIG	0–7	Selects the chip-select where ECC is computed
ECC16B	GPMC_ECC_CONFIG	0/1	Selects column number for ECC calculation
ECCCLEAR	GPMC_ECC_CONTROL	0–7	Clears all ECC result registers
ECCPOINTER	GPMC_ECC_CONTROL	0–7	A write to this bit field selects the ECC result register where the first ECC computation is stored. Set to 1 by default.
ECCSIZE1	GPMC_ECC_SIZE_CONFIG	0x00–0xFF	Defines ECCSIZE1
ECCSIZE0	GPMC_ECC_SIZE_CONFIG	0x00–0xFF	Defines ECCSIZE0
ECCjRESULTSIZES (j from 1 to 9)	GPMC_ECC_SIZE_CONFIG	0/1	Selects the size of ECCn result register
ECCENABLE	GPMC_ECC_CONFIG	1	Enables the ECC computation

11.1.5.14.3.1.3 ECC Computation

The ECC algorithm is a multiple parity bit accumulation computed on the odd and even bit streams extracted from the byte or Word 16 streams. The parity accumulation is split into row and column accumulations, as shown in Figure 11-26 and Figure 11-27. The intermediate row and column parities are used to compute the upper level row and column parities. Only the final computation of each parity bit is used for ECC comparison and correction.

P1o = bit7 XOR bit5 XOR bit3 XOR bit1 on each byte of the data stream

P1e = bit6 XOR bit4 XOR bit2 XOR bit0 on each byte of the data stream

P2o = bit7 XOR bit6 XOR bit3 XOR bit2 on each byte of the data stream

P2e = bit5 XOR bit4 XOR bit1 XOR bit0 on each byte of the data stream

P4o = bit7 XOR bit6 XOR bit5 XOR bit4 on each byte of the data stream

P4e = bit3 XOR bit2 XOR bit1 XOR bit0 on each byte of the data stream

Each column parity bit is XORed with the previous accumulated value.

Figure 11-26. Hamming Code Accumulation Algorithm (1/2)

gpmc-026

For line parities, the bits of each new data are XORed together, and line parity bits are computed as described below:

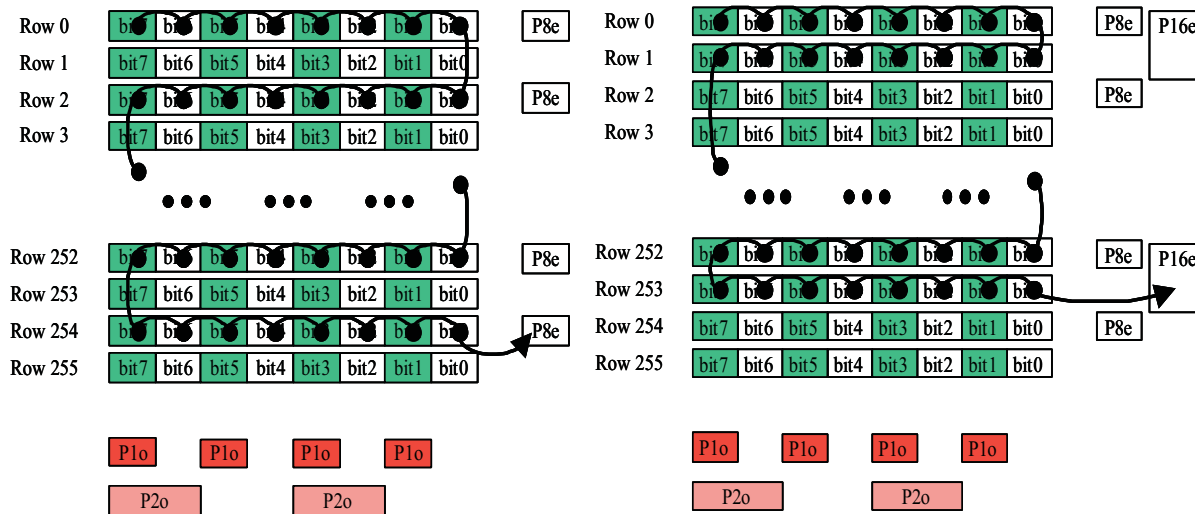

P8e = row0 XOR row2 XOR row4 XOR XOR row254

P8o = row1 XOR row3 XOR row5 XOR XOR row255

P16e = row0 XOR row1 XOR row4 XOR row5 XOR XOR row252 XOR row 253

P16o = row2 XOR row3 XOR row6 XOR row7 XOR XOR row254 XOR row 255

Figure 11-27. Hamming Code Accumulation Algorithm (2/2)

gpmc-027

Unused parity bits in the result registers are set to 0.

Figure 11-28 shows ECC computation for a 256-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and sixteen row parity bits (P8o-P16o-P32o--P1024o for odd parities, and P8e-P16e-P32e--P1024e for even parities).

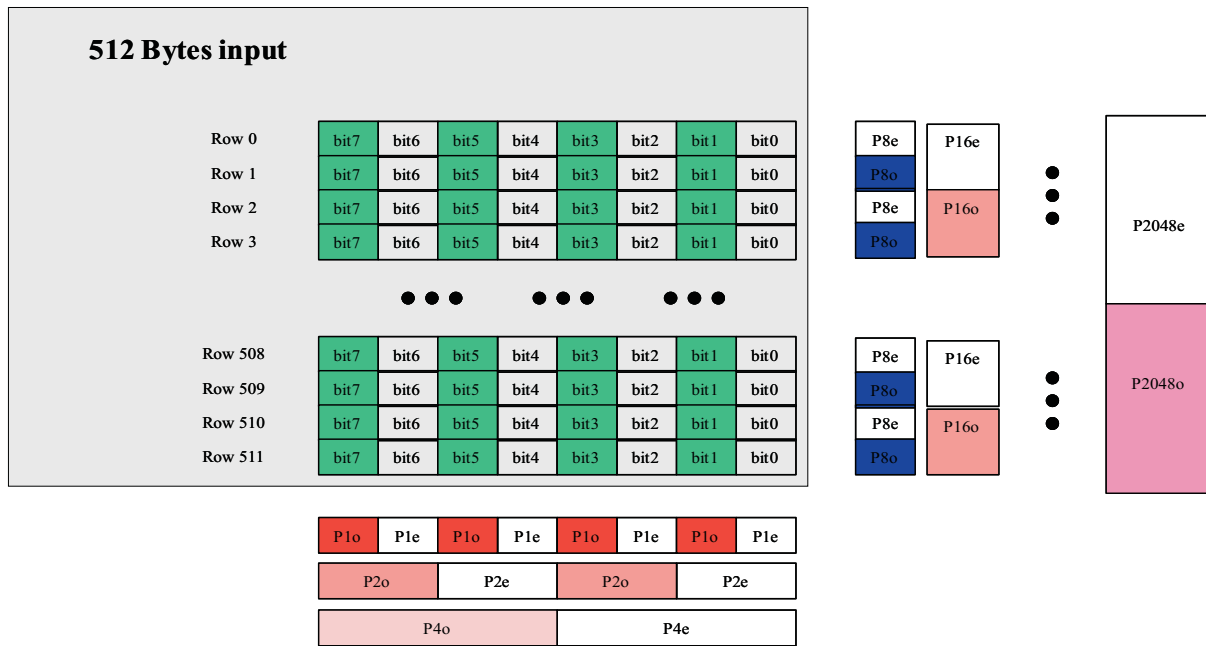

Figure 11-28. ECC Computation for a 256-Byte Data Stream (Read or Write)

gpmc-028

Figure 11-29 shows ECC computation for a 512-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and eighteen row parity bits (P8o-P16o-P32o--P1024o- - P2048o for odd parities, and P8e-P16e-P32e--P1024e- P2048e for even parities).

Figure 11-29. ECC Computation for a 512-Byte Data Stream (Read or Write)

gpmc-029

For a 2-Kbytes page, four 512-byte ECC calculations plus one for the spare area are required. Results are stored in the [GPMC\\_ECCj\\_RESULT](#) registers ( $j = 1$  to 9).

#### 11.1.5.14.3.1.4 ECC Comparison and Correction

To detect an error, the computed ECC result must be XORed with the parity value stored in the spare area of the accessed page.

- If the result of this logical XOR is all 0s, no error is detected and the read data is correct.
- If every second bit in the parity result is a 1, one bit is corrupted and is located at bit address (P2048o, P1024o, P512o, P256o, P128o, P64o, P32o, P16o, P8o, P4o, P2o, P1o). The software must correct the corresponding bit.
- If only one bit in the parity result is 1, it is an ECC error and the read data is correct.

#### 11.1.5.14.3.1.5 ECC Calculation Based on 8-Bit Word

The 8-bit based ECC computation is used for 8-bit wide NAND device interfacing.

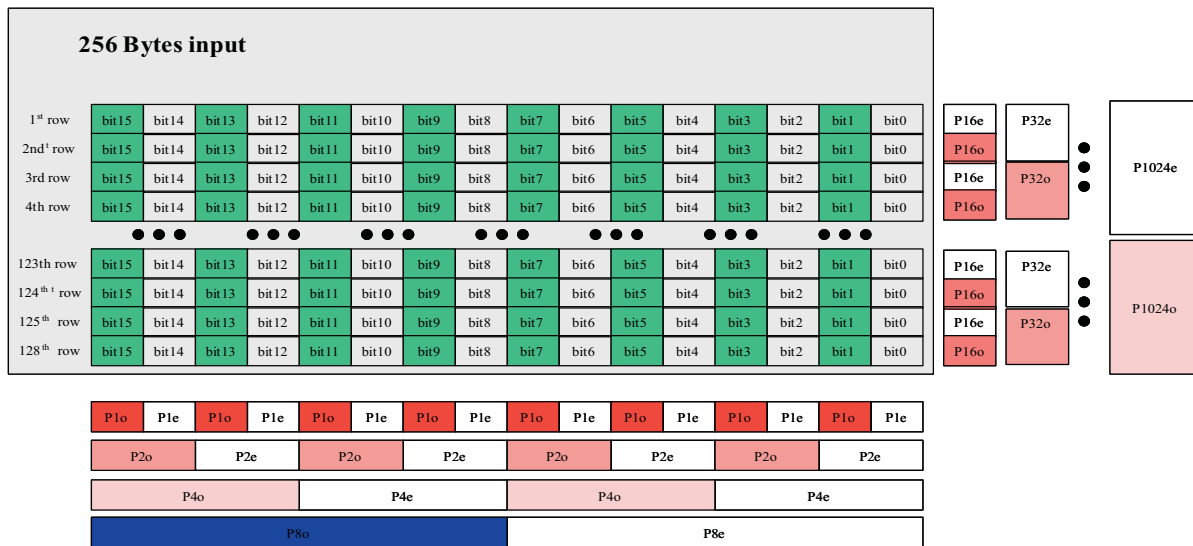

The 8-bit based ECC computation can be used for 16-bit wide NAND device interfacing to get backward compatibility on the error-handling strategy used with 8-bit wide NAND devices. In this case, the 16-bit wide data read from or written to the NAND device is fragmented into 2 bytes. According to little-endian access, the least significant bit (LSB) of the 16-bit wide data is ordered first in the byte stream used for 8-bit based ECC computation.

#### 11.1.5.14.3.1.6 ECC Calculation Based on 16-Bit Word

ECC computation based on a 16-bit word is used for 16-bit wide NAND device interfacing. This ECC computation is not supported when interfacing an 8-bit wide NAND device, and the `GPMC.GPMC_ECC_CONFIG[7]` ECC16B bit must be set to 0 when interfacing an 8-bit wide NAND device.

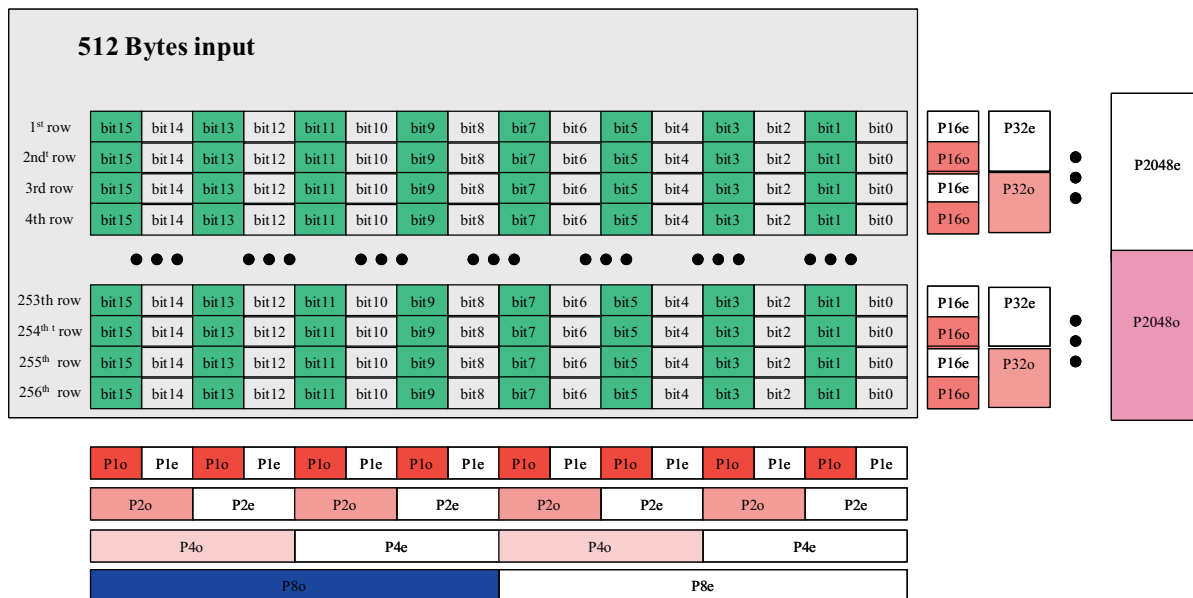

The parity computation based on 16-bit words affects the row and column parity mapping. The main difference is that the odd and even parity bits P8o and P8e are computed on rows for an 8-bit based ECC while there are computed on columns for a 16-bit based ECC. [Figure 11-30](#) and [Figure 11-31](#) show a 128 Word 16 ECC computation scheme and a 256 Word16 ECC computation scheme.

Figure 11-30. 128 Word16 ECC Computation

gpmc-030

Figure 11-31. 256 Word16 ECC Computation

gpmc-031

### 11.1.5.14.3.2 BCH Code

All references to ECC in this section refer to the 4- or 8-bit error correction BCH code.

#### 11.1.5.14.3.2.1 Requirements

1. Read and write accesses to a NAND flash take place by whole pages, in a predetermined sequence: first, the data byte page itself, then some spare bytes, including the BCH ECC (and other information). The NAND IC can cache a full page, including spares, for read and write accesses.

Typical page write sequence:

- Sequential write to NAND cache of main data + spare data, for a page. ECC is calculated on the fly. Calculated ECC may be inserted on the fly in the spares, or replaced by dummy accesses.

- When the calculated ECC is replaced by dummy accesses, it must be written to the cache in a second, separate phase. The ECC module is disabled during that time.
- NAND writes its cache line (page) to the array.

Typical page read sequence:

- Sequential read of a page. ECC is calculated on-the-fly.
  - ECC module buffers status determines the presence of errors.
2. Accesses to several memories may be interleaved by the GPMC, but only one of those memories can be a NAND using the BCH engine at a time; in other words, only one BCH calculation (for example, for a single page) can be on-going at any time. Note also that the sequential nature of NAND accesses guarantees that the data is always written / read out in the same order. BCH-relevant accesses are selected by the GPMCs chip-select.
 

The BCH module has the capacity to store all remainders internally. After the page start, an internal counter is used to detect the 512-byte sector boundaries. On those boundaries, the current remainder is stored and the divider reset for the next calculation. At the end of the page, the BCH module contains all remainders.
  3. Each page may hold up to 4 Kbytes of data, spare bytes not included. This means up to  $8 \times 512$ -byte BCH messages. Since all the data is written / read out first, followed by the BCH ECC, this means that the BCH engine must be able to hold 8 104-bit remainders or syndromes (or smaller, 52-bit ones) at the same time.
 

The BCH module has the capacity to store all remainders internally. After the page start, an internal counter is used to detect the 512-byte sector boundaries. On those boundaries, the current remainder is stored and the divider reset for the next calculation. At the end of the page, the BCH module contains all remainders.
  4. NAND access cycles hold 8 or 16 bits of data each (1 or 2 bytes); Each NAND cycle takes at least 4 cycles of the GPMCs internal clock. This means the NAND flash timing parameters must define a RDCYCLETIME and a WRCYCLETIME of at least 4 clock cycles after optimization when using the BCH calculator.
  5. The spare area is assumed to be large enough to hold the BCH ECC, that is, to have at least a message of 13 bytes available per 512-byte sector of data. The zone of unused spare area by the ECC may or may not be protected by the same ECC scheme, by extending the BCH message beyond 512 bytes (maximum codeword is 1023-byte long, ECC included, which leaves a lot of space to cover some spares bytes).

#### 11.1.5.14.3.2.2 Memory-Mapping of the BCH Codeword

BCH encoding considers a block of data to protect as a polynomial message  $M(x)$ . In our standard case, 512 bytes of data (that is,  $2^{12}$  bits = 4096 bits) are seen as a polynomial of degree  $2^{12} - 1 = 4095$ , with parameters ranging from  $M_0$  to  $M_{4095}$ . For 512 bytes of data, 52 bits are required for 4-bit error correction, and 104 bits are required for 8-bit error correction. The ECC is a remainder polynomial  $R(x)$  of degree 103 (or 51, depending on the selected mode). The complete codeword  $C(x)$  is the concatenation of  $M(x)$  and  $R(x)$  as shown in [Table 11-6](#).

**Table 11-6. Flattened BCH Codeword Mapping (512 Bytes + 104 Bits)**

	Message $M(x)$			ECC $R(x)$		
Bit number	M4095	...	M0	R103	...	R0

If the message is extended by the addition of spare bytes to be protected by the same ECC, the principle is still valid. For example, a 3-byte extension of the message gives a polynomial message  $M(x)$  of degree  $((512 + 3) * 8) - 1 = 4119$ , for a total of  $3+13 = 16$  spare bytes of spare, all protected as part of the same codeword.

The message and the ECC bits are manipulated and mapped in the GPMC byte-oriented system. The ECC bits are stored in [GPMC\\_BCH\\_RESULT0\\_i](#), [GPMC\\_BCH\\_RESULT1\\_i](#), [GPMC\\_BCH\\_RESULT2\\_i](#), and [GPMC\\_BCH\\_RESULT3\\_i](#) (where  $i = 0$  to 7).

#### 11.1.5.14.3.2.2.1 Memory-Mapping of the Data Message

The data message mapping shall follow the following rules:

- Bit endianness within a byte is little-endian, that is, the bytes LS bit is also the lowest-degree polynomial parameter: a byte  $b_7$ - $b_0$  (with  $b_0$  the LS bit) represents a segment of polynomial  $b_7 * x^{(7+i)} +$

$$b_6 * x^{(6+i)} + \dots + b_0 * x^i$$

- The message is mapped in the NAND starting with the highest-order parameters, that is, in the lowest addresses of a NAND page.
- Byte endianness within the NANDs 16-bit words is big endian. This means that the same message mapped in 8- and 16-bit memories has the same content at the same byte address.

**NOTE:** The BCH module has no visibility over actual addresses. The most important point is the sequence of data word the BCH sees. However, the NAND page is always scanned incrementally in read and write accesses, which produces the mapping patterns described in the following.

Table 11-7 and Table 11-8 describe the mapping of the same 512-byte vector (typically a BCH message) in the NAND memory space. The byte "address" is only an offset modulo 512 (0x200), because the same page may contain several contiguous 512-byte sectors (BCH blocks). The LSB and MSB are respectively the bits  $M_0$  and  $M_{(2^{12}-1)}$  of the codeword mapping given previously. In both cases the data vectors are aligned; that is, their boundaries coincide with the RAMs data word boundaries.

**Table 11-7. Aligned Message Byte Mapping in 8-bit NAND**

Byte Offset	8-Bit Word
0x000	(msb) Byte 511 (0x1FF)
0x001	Byte 510 (0x1FE)
...	...
0x1FF	Byte 0 (0x0) (lsb)

**Table 11-8. Aligned Message Byte Mapping in 16-bit NAND**

Byte Offset	16-Bit Word MSB	16-Bit Word LSB
0x000	Byte 510 (0x1FE)	(msb) Byte 511 (0x1FF)
0x002	Byte 508 (0x1FC)	Byte 509 (0x1FD)
...	...	...
0x1FE	Byte 0 (0x0)	(lsb) Byte 1 (0x1)

Table 11-9 through Table 11-14 show the mapping in memory of arbitrarily-sized messages, starting on access (byte or 16-bit word) boundaries for more clarity. The message may actually start and stop on arbitrary nibbles. A nibble is a 4-bit entity. The unused nibbles are not discarded; they can still be used by the BCH module, but as part of the next message section (for example, on another sector ECC).

**Table 11-9. Aligned Nibble Mapping of Message in 8-bit NAND**

Byte Offset	8-Bit Word	
	4-Bit Most Significant Nibble	4-Bit Less Significant Nibble
1	(msb) Nibble S-1	Nibble S-2

Byte Offset	16-Bit Word			
	4-Bit Most Significant Nibble		4-bit less significant Nibble	
0	Nibble S-3	Nibble S-4	(msb) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
...	...	...	...	...
$(S+1)/2 - 4$	Nibble 4	Nibble 3	Nibble 6	Nibble 5
$(S+1)/2 - 2$	Nibble 0 (lsb)		Nibble 2	Nibble 1

**Table 11-13. Misaligned Nibble Mapping of Message in 16-bit NAND (2 Unused Nibbles)**

Byte Offset	16-Bit Word			
	4-Bit Most Significant Nibble		4-Bit Less Significant Nibble	
0	Nibble S-3	Nibble S-4	(msb) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
...	...	...	...	...
$(S+2)/2 - 4$	Nibble 3	Nibble 2	Nibble 5	Nibble 4
$(S+2)/2 - 2$			Nibble 1	Nibble 0 (lsb)

**Table 11-14. Misaligned Nibble Mapping of Message in 16-bit NAND (3 Unused Nibbles)**

Byte Offset	16-Bit Word			
	4-Bit Most Significant Nibble		4-Bit Less Significant Nibble	
0	Nibble S-3	Nibble S-4	(msb) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
...	...	...	...	...
$(S+3)/2 - 4$	Nibble 2	Nibble 1	Nibble 4	Nibble 3
$(S+3)/2 - 2$			Nibble 0 (lsb)	

Many cases exist other than the ones previously given; for example, where the message does not start on a word boundary.

#### 11.1.5.14.3.2.2 Memory-Mapping of the ECC

The ECC (or remainder) is presented by the BCH module as a single 104-bit (or 52-bit), little-endian vector. It is up to the software to fetch those 13 bytes (or 6 ½ bytes) from the modules interface, and then store them to the NAND spare area (page write) or to an intermediate buffer for comparison with the stored ECC (page read). There are no constraints on the ECC mapping inside the spare area: it is software-controlled.

However, it is advised to maintain a coherence in the respective formats of the message or the ECC remainder once they have been read out of the NAND. The error correction algorithm works from the complete codeword (concatenated message and remainder) once an error as been detected. The creation of this codeword must be made as straightforward as possible.

There are cases where the same NAND access contains both data and the ECC protecting that data. This is the case when the data/ECC boundary (which can be on any nibble) does not coincide with an access boundary. The ECC is calculated on-the-fly following the write. In that case, the write must also contain part of the ECC because it is impossible to insert the ECC on-the-fly. Instead:

- During the initial page write (BCH encoding), the ECC is replaced by dummy bits. The BCH encoder is by definition turned OFF during the ECC section, so the BCH result is unmodified.
- During a second phase, the ECC is written to the correct location, next to the actual data.
- The completed line buffer is then written to the NAND array.

#### 11.1.5.14.3.2.3 Wrapping Modes

For a given wrapping mode, the module automatically goes through a specific number of sections, as data is being fed into the module. For each section, the BCH core can be enabled (in which case the data is fed to the BCH divider) or not (in which case the BCH simply counts to the end of the section). When enabled, the data is added to the ongoing calculation for a given sector number (for example, number 0).

Wrapping modes are described below. To get a better understanding and see the real-life read and write sequences implemented with each mode, see [Section 11.1.5.14.3.2.3](#).

For each mode:

- A sequence describes the mode in pseudo-language, with the size and the buffer used for ECC processing (if ON) for each section. The programmable lengths are size, size0, and size1.
- A checksum condition is given. If the checksum condition is not respected for a given mode, the module behavior is unpredictable. S is the number of sectors in the page; size0 and size1 are the section sizes programmed for the mode, in nibbles.

Wrapping modes 8, 9, 10, and 11 insert a 1-nibble padding where the BCH processing is OFF. This is intended for  $t = 4$  ECC, where ECC is 6 ½ bytes long and the ECC area is expected to include (at least) one unused nibble to remain byte-aligned.

#### 11.1.5.14.3.2.4 Manual Mode (0x0)

This mode is intended for short sequences, added manually to a given buffer through the software data port input. A complete page may be built out of several such sequences.

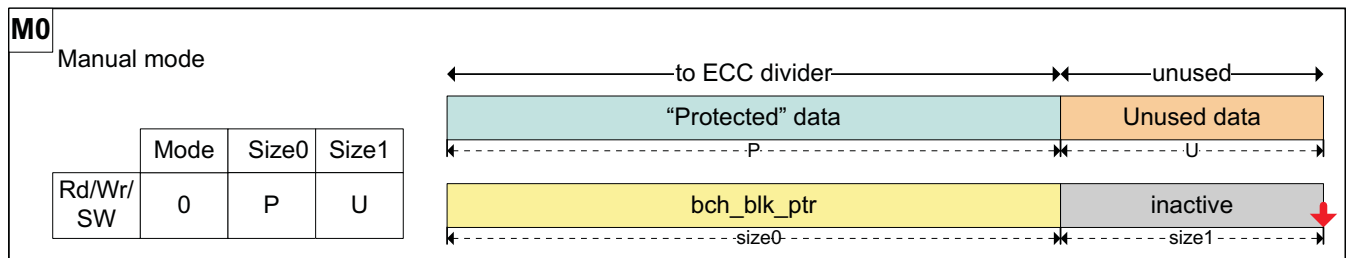

To process an arbitrary sequence of 4-bit nibbles, accesses to the software data port shall be made, containing the appropriate data. If the sequence end does not coincide with an access boundary (for example, to process 5 nibbles = 20 bits in 16-bit access mode) and those nibbles need to be skipped, a number of unused nibbles shall be programmed in size1 (in the same example: 5 nibbles to process + 3 to discard = 8 nibbles = exactly 2 x 16-bit accesses: we must program size0 = 5, size1 = 3).

---

**NOTE:** In the following figures size and size0 are the same parameter.

---

Figure 11-32. Manual Mode Sequence and Mapping

gpmc-032

Section processing sequence:

- One time with buffer
  - size0 nibbles of data, processing ON
  - size1 nibbles of unused data, processing OFF

Checksum: size0 + size1 nibbles must fit in a whole number of accesses.

#### 11.1.5.14.3.2.2.5 Mode 0x1

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S - (size0 + size1)

#### 11.1.5.14.3.2.2.6 Mode 0xA (10)

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
  - 1 nibble pad spare, processing OFF
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S - (size0 + 1 + size1)

#### 11.1.5.14.3.2.2.7 Mode 0x2

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S - (size0 + size1)

#### 11.1.5.14.3.2.2.8 Mode 0x3

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - size1)

#### 11.1.5.14.3.2.2.9 Mode 0x7

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = size0 + (S - size1)

#### 11.1.5.14.3.2.2.10 Mode 0x8

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - (1+size1))

#### 11.1.5.14.3.2.2.11 Mode 0x4

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time (no buffer used)
  - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - size1)

#### 11.1.5.14.3.2.2.12 Mode 0x9

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON

- One time (no buffer used)
  - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - (1+size1))

#### 11.1.5.14.3.2.2.13 Mode 0x5

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S - (size0 + size1)

#### 11.1.5.14.3.2.2.14 Mode 0xB (11)

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S - (size0 + 1 + size1)

#### 11.1.5.14.3.2.2.15 Mode 0x6

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S - (size0 + size1)

#### 11.1.5.14.3.2.3 Supported NAND Page Mappings and ECC Schemes

The following rules apply throughout the entire mapping description:

- Main data area (sectors) size is hardcoded to 512 bytes.
- Spare area size is programmable.
- All page sections (of main area data bytes, protected spare bytes, unprotected spare bytes, and ECC) are defined as explained in [Section 11.1.5.14.3.2.2.1](#).

Each one of the following sections shows a NAND page mapping example (per-sector spare mappings, pooled spare mapping, per-sector spare mapping, with ECC separated at the end of the page).

In the mapping diagrams, sections that belong to the same BCH codeword have the same color (blue or green); unprotected sections are not covered (orange) by the BCH scheme.

Below each mapping diagram, a write (encoding) and read (decoding: syndrome generation) sequence is given, with the number of the active buffers at each point in time (yellow). In the inactive zones (grey), no computing is taking place but the data counter is still active.

A table on the left summarizes the mode, size0, size1 parameters to program for respectively write and read processing of a page, with the given mapping, where :

- P is the size of spare byte section Protected by the ECC (in nibbles)
- U is the size of spare byte section Unprotected by the ECC (in nibbles)
- E is the size of the ECC itself (in nibbles)
- S is the number of Sectors per page (2 in the current diagrams)

Each time the processing of a BCH block is complete (ECC calculation for write/encoding, syndrome generation for read/decoding, indicated by red arrows), the update pointer is pulsed. Note that the processing for block 0 can be the first or the last to complete, depending on the NAND page mapping and operation (read or write). All examples show a page size of 1kByte + spares; that is, S = 2 sectors of 512 bytes. The same principles can be extended to larger pages by adding more sectors.

The actual BCH codeword size is used during the error location work to restrict the search range: by definition, errors can only happen in the codeword that was actually written to the NAND, and not in the mathematical codeword of  $n = 2^{13} - 1 = 8191$  bits. That codeword (higher-order bits) is all-zero and implicit during computations.

The actual BCH codeword size depends on the mode, programmed sizes, and sector number (all sizes in nibbles):

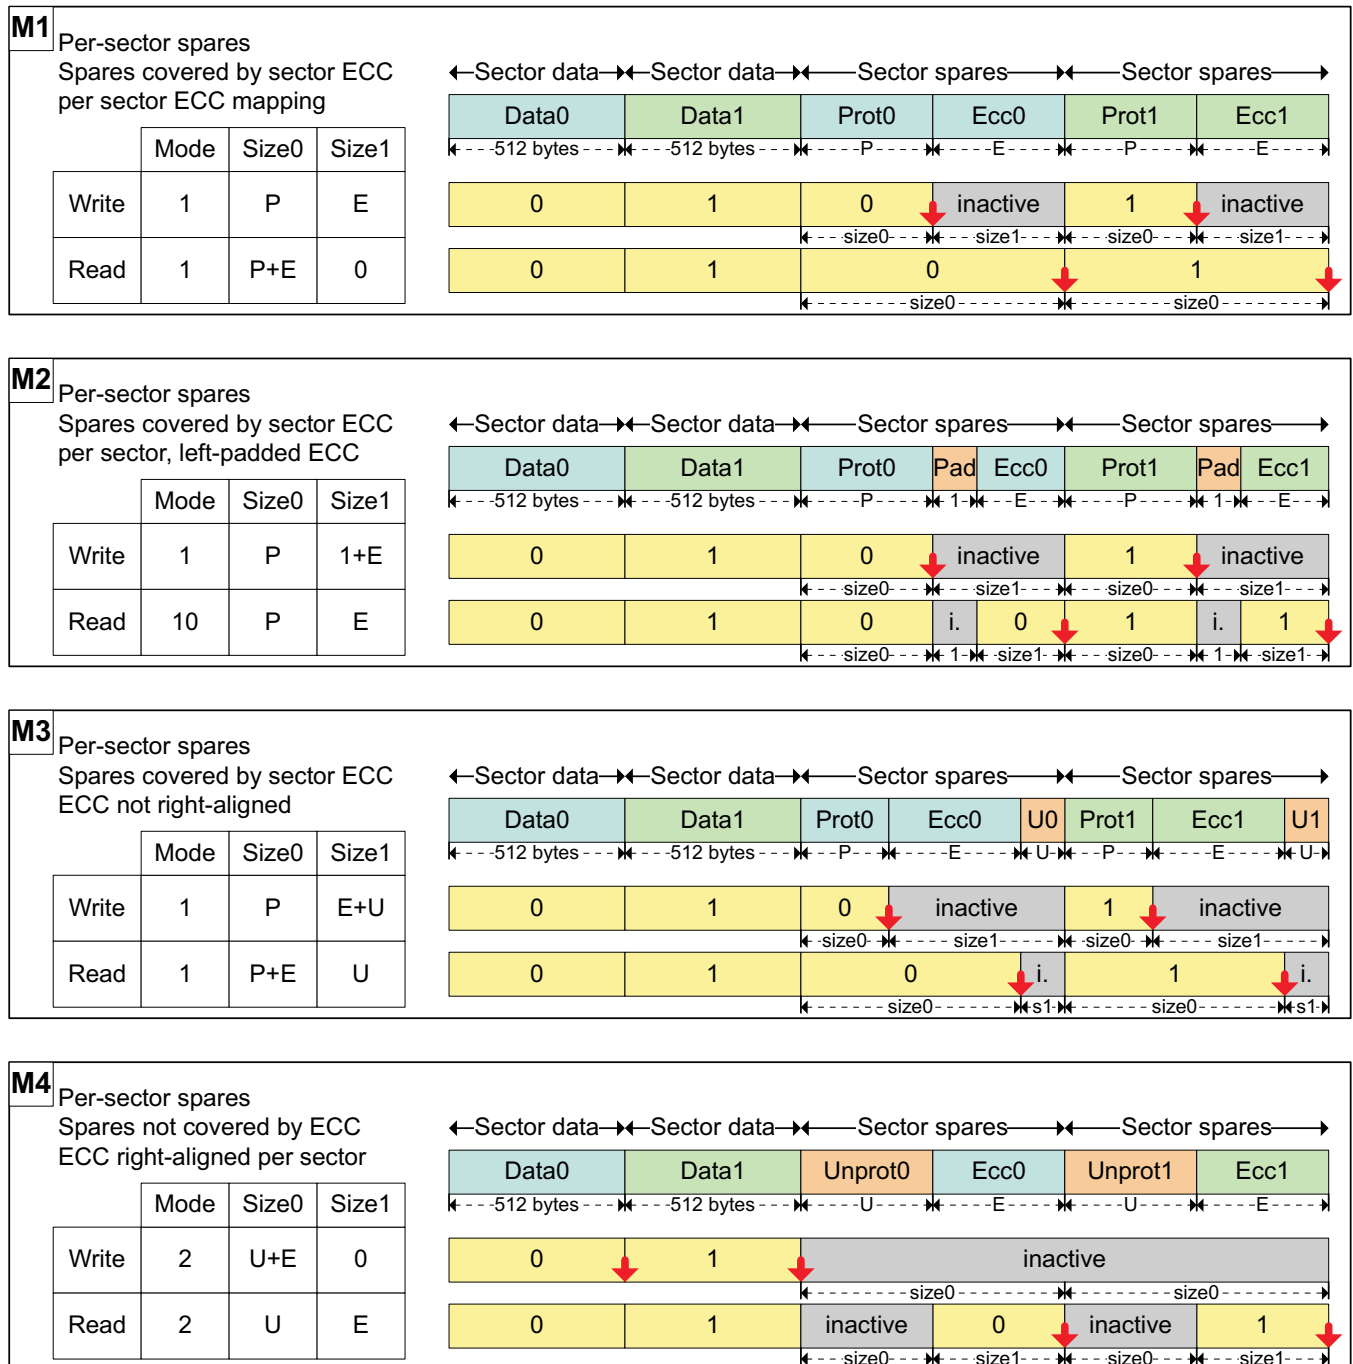

- Spares mapped and protected per sector (below: see M1-M2-M3-M9-M10):
  - all sectors:  $(512) + P + E$
- Spares pooled and protected by sector 0 (below: see M5-M6):
  - sector 0 codeword:  $(512) + P + E$
  - other sectors:  $(512) + E$
- Unprotected spares (below: see M4-M7-M8-M11-M12):
  - all codewords  $(512) + E$

#### **11.1.5.14.3.2.3.1 Per-Sector Spare Mappings**

In the schemes in [Figure 11-33](#), each 512-byte sector of the main area has its own dedicated section of the spare area. The spare area of each sector is composed of :

- ECC, which must be located after the data it protects
- Other data, which may or may not be protected by the sector ECC

Figure 11-33. NAND Page Mapping and ECC: Per-Sector Schemes

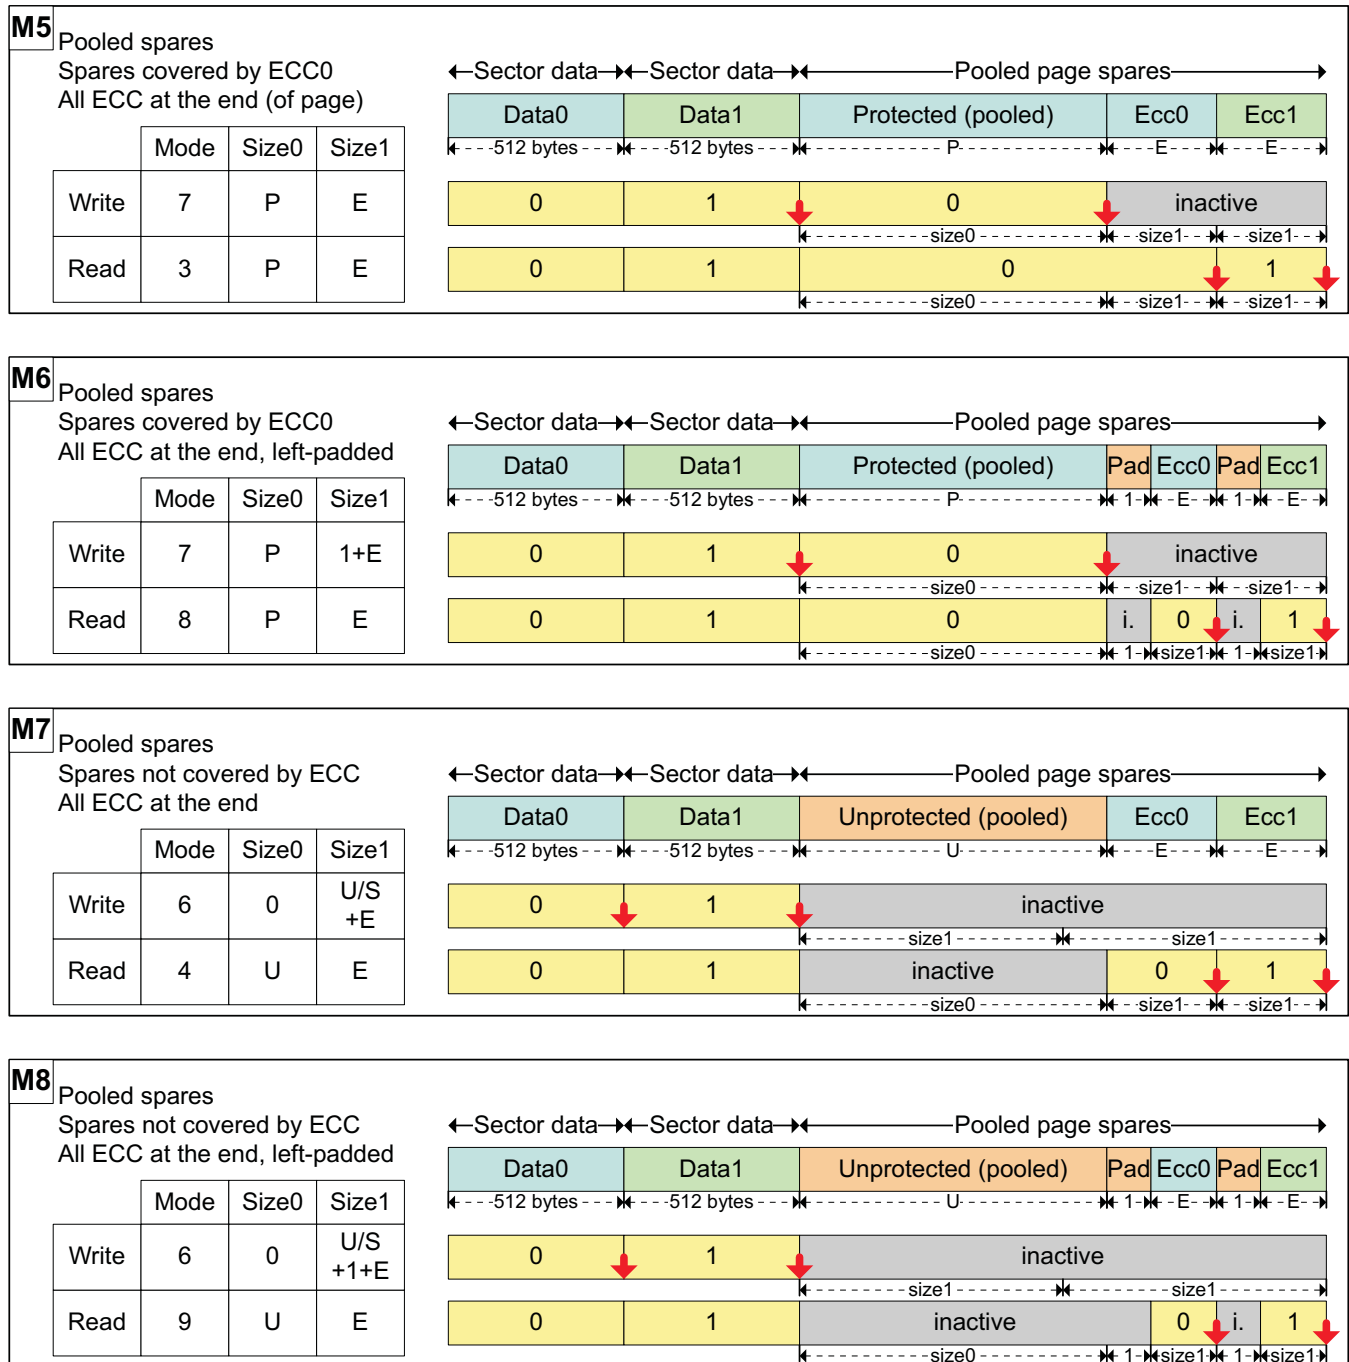

gpmc-033

### 11.1.5.14.3.2.3.2 Pooled Spare Mapping

In the schemes in Figure 11-34, the spare area is pooled for the page.

- The ECC of each sector is aligned at the end of the spare area.
- The non-ECC spare data may or may not be covered by the ECC of sector 0.

Figure 11-34. NAND Page Mapping and ECC: Pooled Spare Schemes

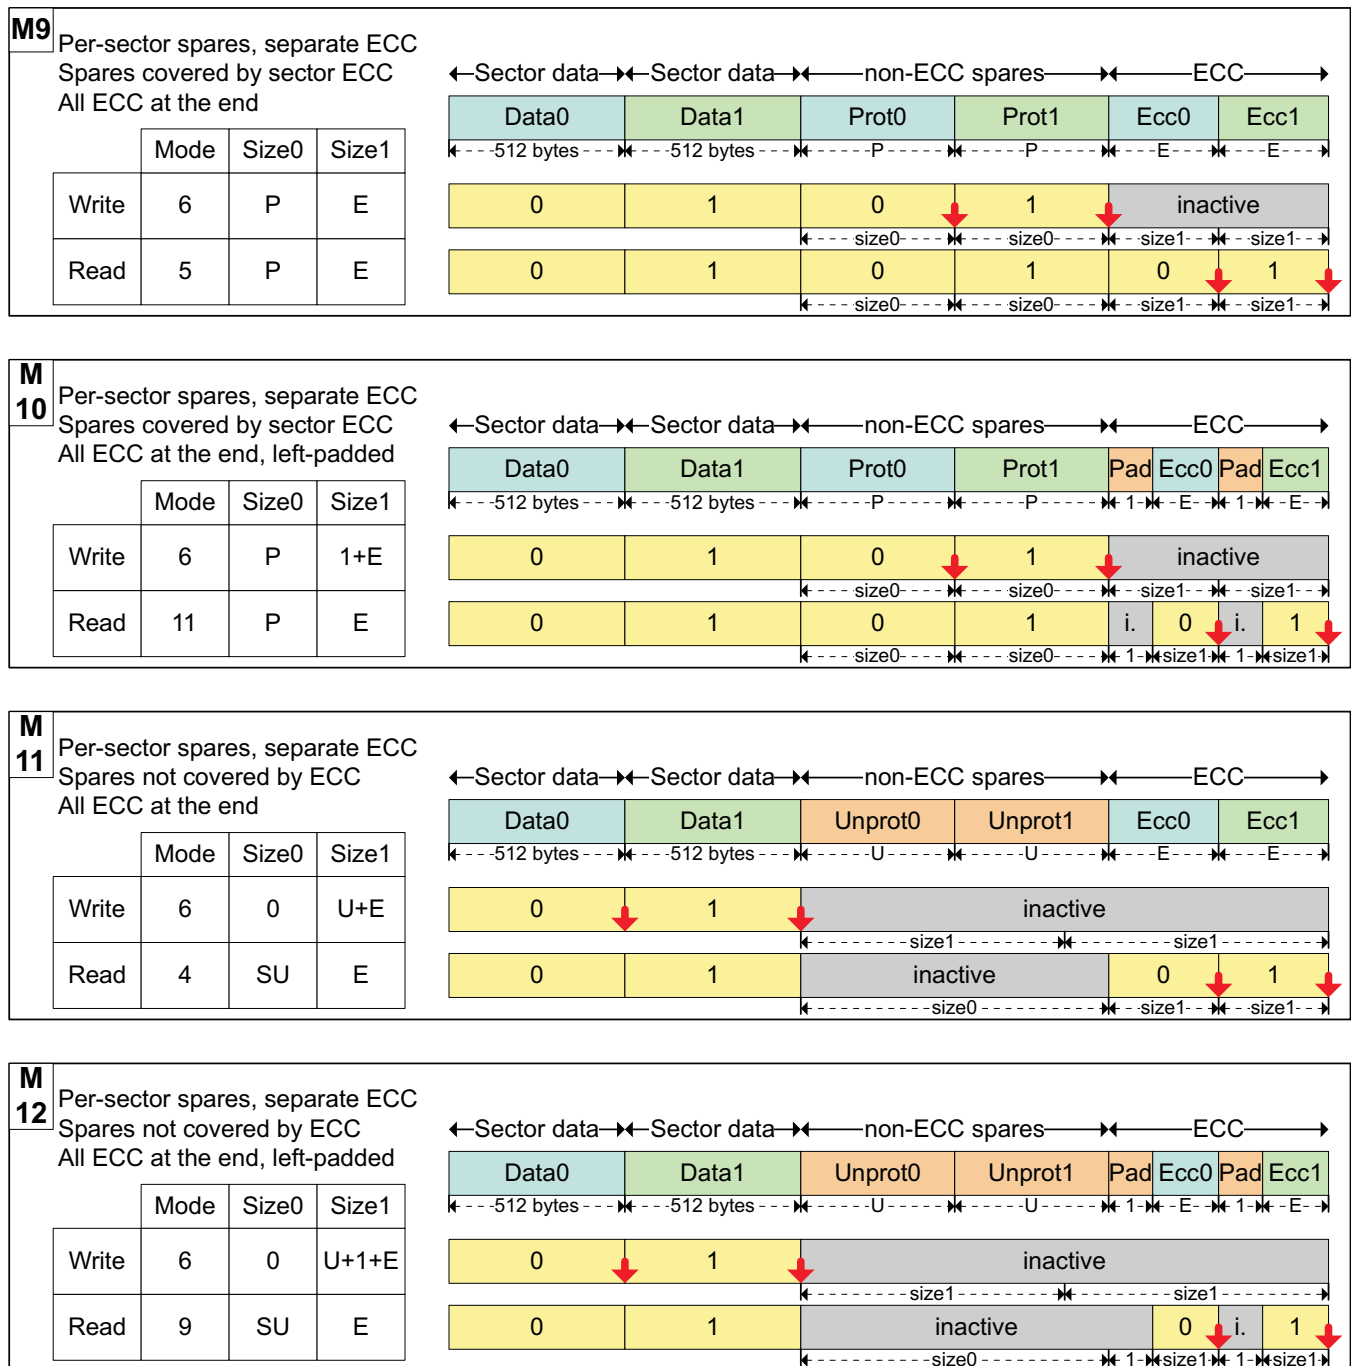

gpmc-034

11.1.5.14.3.2.3.3 Per-Sector Spare Mapping, With ECC Separated at the End of the Page

In the schemes in Figure 11-35, each 512-byte sector of the main area is associated with two sections of the spare area.

- ECC section, all aligned at the end of the page
- Other data section, aligned before the ECCs, each of which may or may not be protected by its sectors ECC

Figure 11-35. NAND Page Mapping and ECC: Per-Sector Schemes, With Separate ECC

gpmc\_035

#### 11.1.5.14.4 Prefetch and Write-Posting Engine

NAND device data access cycles are usually much slower than the MCU system frequency; such NAND read or write accesses issued by the processor will impact the overall system performance, especially considering long read or write sequences required for NAND page loading or programming. To minimize this effect on system performance, the GPMC includes a prefetch and write-posting engine, which can be used to read from or write to any chip-select location in a buffered manner.

The prefetch and write-posting engine uses an embedded 64 bytes (32 Word16) FIFO to prefetch data from the NAND device in read mode (prefetch mode) or to store host data to be programmed into the NAND device in write mode (write-posting mode). The FIFO draining and filling (read and write) can be controlled either by the MCU through interrupt synchronization (an interrupt is triggered whenever a programmable threshold is reached) or the sDMA through DMA request synchronization, with a programmable request byte size in both prefetch or posting mode.

The prefetch and write-posting engine includes a single memory pool. Therefore, only one mode, read or write, can be used at any given time. In other words, the prefetch and write-posting engine is a single-context engine that can be allocated to only one chip-select at a time for a read prefetch or a write-posting process.

The engine does not support atomic command and address phase programming and is limited to linear memory read or write access. In consequence, it is limited to NAND data-stream access. The engine relies on the MCU NAND software driver to control block and page opening with the correct data address pointer initialization, before the engine can read from or write to the NAND memory device.

Once started, the engine data reads and writes sequencing is solely based on FIFO location availability and until the total programmed number of bytes is read or written.

Any host-concurrent accesses to a different chip-select are correctly interleaved with ongoing engine accesses. The engine has the lowest priority access so that host accesses to a different chip-select do not suffer a large latency.

A round-robin arbitration scheme can be enabled to ensure minimum bandwidth to the prefetch and write-posting engine in the case of back-to-back direct memory requests to a different chip-select. If the GPMC.GPMC\_PREFETCH\_CONFIG1[23] PFPWENROUNDROBIN bit is enabled, the arbitration grants the prefetch and write posting engine access to the GPMC bus for a number of requests programmed in the GPMC.GPMC\_PREFETCH\_CONFIG1[19:16] PFPWWEIGHTEDPRIO field.

The prefetch and write-posting engine is dedicated to data-stream access (as opposed to random data access). The engine does not include an address generator, and the request is limited to chip-select target identification. The prefetch/write-posting engine read or write request is routed to the access engine with the chip-select destination ID. After the required arbitration phase, the access engine processes the request as a single access with the data access size equal to the device size specified in the corresponding chip-select configuration.

---

**NOTE:** The destination chip-select configuration must be set to the NAND protocol-compatible configuration for which address lines are not used (the address bus is not changed from its current value). Selecting a different chip-select configuration can produce undefined behavior.

---

#### 11.1.5.14.4.1 General Basic Programming Model

The engine can be configured only if the GPMC.GPMC\_PREFETCH\_CONTROL[0] STARTENGINE bit is de-asserted.

The engine must be correctly configured in prefetch or write-posting mode and must be linked to a NAND chip-select before it can be started. The chip-select is linked using the GPMC.GPMC\_PREFETCH\_CONFIG1[26:24] ENGINECSSELECTOR field.

In both prefetch and write-posting modes, the engine respectively uses byte or Word16 access requests for an 8- or 16-bit wide NAND device attached to the linked chip-select. The FIFOTHRESHOLD and TRANSFERCOUNT fields must be programmed accordingly as a number of bytes.

When the GPMC.GPMC\_PREFETCH\_CONFIG1[7] ENABLEENGINE bit is set, the FIFO entry on the L3 interconnect port side is accessible at any address in the associated chip-select memory region. When the ENABLEENGINE bit is set, any host access to this chip-select is rerouted to the FIFO input. Directly accessing the NAND device linked to this chip-select from the host is still possible through the GPMC.GPMC\_NAND\_COMMAND\_i, GPMC.GPMC\_NAND\_ADDRESS\_i, and GPMC.GPMC\_NAND\_DATA\_i registers (where i = 0 to 7).

The FIFO entry on the L3 interconnect port can be accessed with Byte, Word16, or Word32 access size, according to little-endian format, even though the FIFO input is 32-bit wide.

The FIFO control is made easier through the use of interrupts or DMA requests associated with the FIFOTHRESHOLD bit field. The GPMC.GPMC\_PREFETCH\_STATUS[30:24] FIFOPointer field monitors the number of available bytes to be read in prefetch mode or the number of free empty slots which can be written in write-posting mode. The GPMC.GPMC\_PREFETCH\_STATUS[13:0] COUNTVALUE field monitors the number of remaining bytes to be read or written by the engine according to the TRANSFERCOUNT value. The FIFOPointer and COUNTVALUE bit fields are always expressed as a number of bytes even if a 16-bit wide NAND device is attached to the linked chip-select.

In prefetch mode, when the FIFOPointer equals 0, that is, the FIFO is empty, a host read access receives the byte last read from the FIFO as its response. In case of Word32 or Word16 read accesses, the last byte read from the FIFO is copied the required number of times to fit the requested word size. In write-posting mode, when the FIFOPointer equals 0 (that is, the FIFO is full, a host write overwrites the last FIFO byte location). There is no underflow or overflow error reporting in the GPMC.

#### 11.1.5.14.4.2 Prefetch Mode

The prefetch mode is selected when the GPMC.GPMC\_PREFETCH\_CONFIG1[0] ACCESSMODE bit is cleared.

The MCU NAND software driver must issue the block and page opening (READ) command with the correct data address pointer initialization before the engine can be started to read from the NAND memory device. The engine is started by asserting the GPMC.GPMC\_PREFETCH\_CONTROL[0] STARTENGINE bit. The STARTENGINE bit automatically clears when the prefetch process completes.

If required, the ECC calculator engine must be initialized (configured, reset, and enabled) before the prefetch engine is started, so that the ECC is correctly computed on all data read by the prefetch engine.

When the GPMC.GPMC\_PREFETCH\_CONFIG1[3] SYNCHROMODE bit is cleared, the prefetch engine starts requesting data as soon as the STARTENGINE bit is set. If using this configuration, the host must monitor the NAND device-ready pin so that it only sets the STARTENGINE bit when the NAND device is in a ready state, meaning data is valid for prefetching.

When the GPMC.GPMC\_PREFETCH\_CONFIG1[3] SYNCHROMODE bit is set, the prefetch engine starts requesting data when an active to inactive wait signal transition is detected. The transition detector must be cleared before any transition detection; see [Section 11.1.5.14.2.2](#). The GPMC.GPMC\_PREFETCH\_CONFIG1[5:4] WAITPINSELECTOR field selects which gpmc\_wait pin edge detector triggers the prefetch engine in this synchronized mode.

If the STARTENGINE bit is set after the NAND address phase (page opening command), the engine is effectively started only after the actual NAND address phase completion. To prevent GPMC stall during this NAND address phase, set the STARTENGINE bit field before NAND address phase completion when in synchronized mode. The prefetch engine will start when an active to inactive wait signal transition is detected. The STARTENGINE bit is automatically cleared on prefetch process completion.

The prefetch engine issues a read request to ensure that the FIFO is always filled with as much data as acceptable, until the programmed GPMC.GPMC\_PREFETCH\_CONFIG2[13:0] TRANSFERCOUNT field is completed.

**Table 11-15. Prefetch Mode Configuration**

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	0	Prefetch engine can be configured only if STARTENGINE is set to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1[26:24]	0 to 7	Selects the chip-select associated with a NAND device where the prefetch engine is active.
ACCESSMODE	GPMC_PREFETCH_CONFIG1[0]	0	Selects prefetch mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1[14:8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2[13:0]		Selects the number of bytes to be read or written by the engine to the selected chip-select

**Table 11-15. Prefetch Mode Configuration (continued)**

Bit Field	Register	Value	Comments
SYNCHROMODE	<a href="#">GPMC_PREFETCH_CONFIG1</a> [3]	0/1	Selects when the engine starts the access to the chip-select
WAITPINSELECT	<a href="#">GPMC_PREFETCH_CONFIG1</a> [17:16]	0 to 3	(If SynchroMode = 1) Selects wait pin edge detector
ENABLEOPTIMIZEDACCESS	<a href="#">GPMC_PREFETCH_CONFIG1</a> [27]	0/1	See <a href="#">Section 11.1.5.14.4.6</a> .
CYCLEOPTIMIZATION	<a href="#">GPMC_PREFETCH_CONFIG1</a> [30:28]		
ENABLEENGINE	<a href="#">GPMC_PREFETCH_CONFIG1</a> [7]	1	Engine enabled
STARTENGINE	<a href="#">GPMC_PREFETCH_CONTROL</a> [0]	1	Starts the prefetch engine

#### 11.1.5.14.4.3 FIFO Control in Prefetch Mode

The FIFO can be drained directly by the MPU or by an sDMA channel.

In MPU draining mode, the FIFO status can be monitored through the [GPMC.GPMC\\_PREFETCH\\_STATUS](#)[30:24] FIFOPointer field or through the [GPMC.GPMC\\_PREFETCH\\_STATUS](#)[16] FIFOTHRESHOLDSTATUS bit. The FIFOPointer indicates the current number of available data to be read; FIFOTHRESHOLDSTATUS set to 1 indicates that at least FIFOTHRESHOLD bytes are available from the FIFO.

An interrupt can be triggered by the GPMC if the [GPMC.GPMC\\_IRQENABLE](#)[0] FIFOEVENTENABLE bit is set. The FIFO interrupt event is logged, and the [GPMC.GPMC\\_IRQSTATUS](#)[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, the MPU must read all the available bytes, or at least enough bytes to get below the programmed FIFO threshold, and the FIFOEVENTSTATUS bit must be cleared to enable further interrupt events. The FIFOEVENTSTATUS bit must always be reset prior to asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt generation must be enabled after enabling the STARTENGINE bit.

Prefetch completion can be monitored through the [GPMC.GPMC\\_PREFETCH\\_STATUS](#)[13:0] COUNTVALUE field. COUNTVALUE indicates the number of currently remaining data to be requested according to the TRANSFERCOUNT value. An interrupt can be triggered by the GPMC when the prefetch process is complete (that is, COUNTVALUE equals 0) if the [GPMC.GPMC\\_IRQENABLE](#)[1] TERMINALCOUNTEVENTENABLE bit is set. At prefetch completion, the TERMINALCOUNT interrupt event is also logged, and the [GPMC.GPMC\\_IRQSTATUS](#)[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the MPU must clear the TERMINALCOUNTSTATUS bit. The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

---

**NOTE:** The COUNTVALUE value is only valid when the prefetch engine is active (started), and an interrupt is triggered only when COUNTVALUE reaches 0 (that is, when the prefetch engine automatically goes from an active to inactive state).

---

The number of bytes to be prefetched (programmed in TRANSFERCOUNT) must be a multiple of the programmed FIFOTHRESHOLD to trigger the correct number of interrupts allowing a deterministic and transparent FIFO control. If this guideline is respected, the number of ISR accesses is always required and the FIFO is always empty after the last interrupt is triggered. In other cases, the TERMINALCOUNT interrupt must be used to read the remaining bytes in the FIFO (the number of remaining bytes being lower than the FIFOTHRESHOLD value).

In DMA draining mode, the [GPMC.GPMC\\_PREFETCH\\_CONFIG1](#)[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes are ready to be read from the FIFO. The DMA channel owning this DMA request must be programmed so that the number of bytes programmed in FIFOTHRESHOLD is read from the FIFO during the DMA request process. The DMA request is kept active until this number of bytes has effectively been read from the FIFO, and no other DMA request can be issued until the ongoing active request is complete.

In prefetch mode, the TERMINALCOUNT event is also a source of DMA requests if the number of bytes to be prefetched is not a multiple of FIFOTHRESHOLD, the remaining bytes in the FIFO can be read by the DMA channel using the last DMA request. This assumes that the number of remaining bytes to be read is known and controlled through the DMA channel programming model.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive to active prefetch (the STARTENGINE bit is set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that the out-of-date active DMA request does not trigger spurious DMA transfers.

#### 11.1.5.14.4.4 Write-Posting Mode

The write-posting mode is selected when the GPMC.GPMC\_PREFETCH\_CONFIG1[0] ACCESSMODE bit is set.

The MCU NAND software driver must issue the correct address pointer initialization command (page program) before the engine can start writing data into the NAND memory device. The engine starts when the GPMC.GPMC\_PREFETCH\_CONTROL[0] STARTENGINE bit is set to 1. The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MCU NAND software driver must issue the second cycle program command and monitor the status for programming process completion (adding ECC handling, if required).

If used, the ECC calculator engine must be started (configured, reset, and enabled) before the posting engine is started so that the ECC parities are properly calculated on all data written by the prefetch engine to the associated chip-select.

In write-posting mode, the GPMC.GPMC\_PREFETCH\_CONFIG1[3] SYNCHROMODE bit must be cleared so that posting starts as soon as the STARTENGINE bit is set and the FIFO is not empty.

If the STARTENGINE bit is set after the NAND address phase (page program command), the STARTENGINE setting is effective only after the actual NAND command completion. To prevent GPMC stall during this NAND command phase, set the STARTENGINE bit field before the NAND address completion and ensure that the associated DMA channel is enabled after the NAND address phase.

The posting engine issues a write request when valid data are available from the FIFO and until the programmed GPMC.GPMC\_PREFETCH\_CONFIG2[13:0] TRANSFERCOUNT accesses have been completed.

The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MCU NAND software driver must issue the second cycle program command and monitor the status for programming process completion. The closing program command phase must only be issued when the full NAND page has been written into the NAND flash write buffer, including the spare area data and the ECC parities, if used.

**Table 11-16. Write-Posting Mode Configuration**

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	0	Write-posting engine can be configured only if STARTENGINE is set to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1[26:24]	0 to 7	Selects the chip-select associated with a NAND device where the prefetch engine is active
ACCESSMODE	GPMC_PREFETCH_CONFIG1[0]	1	Selects write-posting mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1[14:8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2[13:0]		Selects the number of bytes to be read or written by the engine from/to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1[3]	0	Engine starts the access to chip-select as soon as STARTENGINE is set.
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1[27]	0/1	See <a href="#">Section 11.1.5.14.4.6</a> .
CYCLEOPTIMIZATION	GPMC_PREFETCH_CONFIG1[30:28]		

**Table 11-16. Write-Posting Mode Configuration (continued)**

Bit Field	Register	Value	Comments
ENABLEENGINE	GPMC_PREFETCH_CONFIG1[7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	1	Starts the prefetch engine

#### 11.1.5.14.4.5 FIFO Control in Write-Posting Mode

The FIFO can be filled directly by the MPU or by an sDMA channel.

In MPU filling mode, the FIFO status can be monitored through the FIFOPINTER or through the GPMC.GPMC\_PREFETCH\_STATUS[16] FIFOTHRESHOLDSTATUS bit. FIFOPINTER indicates the current number of available free byte places in the FIFO, and the FIFOTHRESHOLDSTATUS bit, when set, indicates that at least FIFOTHRESHOLD free byte places are available in the FIFO.

An interrupt can be issued by the GPMC if the GPMC.GPMC\_IRQENABLE[0] FIFOEVENTENABLE bit is set. When the interrupt is fired, the GPMC.GPMC\_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, the MPU must write enough bytes to fill the FIFO, or enough bytes to get below the programmed threshold, and the FIFOEVENTSTATUS bit must be cleared to get further interrupt events. The FIFOEVENTSTATUS bit must always be cleared prior to asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt must be enabled after enabling the STARTENGINE bit.

The posting completion can be monitored through the GPMC.GPMC\_PREFETCH\_STATUS[13:0] COUNTVALUE field. COUNTVALUE indicates the current number of remaining data to be written based on the TRANSFERCOUNT value. An interrupt is issued by the GPMC when the write-posting process completes (that is, COUNTVALUE equal to 0) if the GPMC.GPMC\_IRQENABLE[1] TERMINALCOUNTEVENTENABLE bit is set. When the interrupt is fired, the GPMC.GPMC\_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the MPU must clear the TERMINALCOUNTSTATUS bit. The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

---

**NOTE:** The COUNTVALUE value is valid only if the write-posting engine is active and started, and an interrupt is issued only when COUNTVALUE reaches 0 (that is, when the posting engine automatically goes from active to inactive).

---

In DMA filling mode, the DMAMode bit field in the GPMC.GPMC\_PREFETCH\_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes-free places are available in the FIFO. The DMA channel owning this DMA request must be programmed so that a number of bytes equal to the value programmed in the FIFOTHRESHOLD bit field are written into the FIFO during the DMA access. The DMA request remains active until the associated number of bytes has effectively been written into the FIFO, and no other DMA request can be issued until the ongoing active request has been completed.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive to active prefetch (STARTENGINE set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that an out-of-date active DMA request does not trigger spurious DMA transfers.

In write-posting mode, the DMA or the MPU fill the FIFO with no consideration to the associated byte enables. Any byte stored in the FIFO is written into the memory device.

### 11.1.5.14.4.6 Optimizing NAND Access Using the Prefetch and Write-Posting Engine

Access time to a NAND memory device can be optimized for back-to-back accesses if the associated nCS signal is not deasserted between accesses. The GPMC access engine can track prefetch engine accesses to optimize the access timing parameter programmed for the allocated chip-select, if no accesses to other chip-selects (that is, interleaved accesses) occur. Similarly, the access engine also eliminates the CYCLE2CYCLEDELAY even if CYCLE2CYCLESAMECSEN is set. This capability is limited to the prefetch and write-posting engine accesses, and MPU accesses to a NAND memory device (through the defined chip-select memory region or through the GPMC.GPMC\_NAND\_DATA\_i location, i = 0 to 7) are never optimized.

The GPMC.GPMC\_PREFETCH\_CONFIG1[27] ENABLEOPTIMIZEDACCESS bit must be set to enable optimized accesses. To optimize access time, the GPMC.GPMC\_PREFETCH\_CONFIG1[30:28] CYCLEOPTIMIZATION field defines the number of GPMC\_FCLK cycles to be suppressed from the RDCYCLETIME, WRCYCLETIME, RDACCESSTIME, WRACCESSTIME, CSOFFTIME, ADVOFFTIME, OEOFFTIME, and WEOFFTIME timing parameters.

Figure 11-36 highlights that, in the case of back-to-back accesses to the NAND flash through the prefetch engine, CYCLE2CYCLESAMECSEN is forced to 0 when using optimized accesses. The first access uses the regular timing settings for this chip-select. All accesses after this one use settings reduced by x clock cycles, x being defined by the GPMC\_PREFETCH\_CONFIG1[30:28] CYCLEOPTIMIZATION field.

Figure 11-36. NAND Read Cycle Optimization Timing Description

gpmc-036

#### 11.1.5.14.4.7 Interleaved Accesses Between Prefetch and Write-Posting Engine and Other Chip-Selects

Any on-going read or write access from the prefetch and write-posting engine is completed before an access to any other chip-select can be initiated. As a default, the arbiter uses a fixed-priority algorithm, and the prefetch and write-posting engine has the lowest priority. The maximum latency added to access starting time in this case equals the RDCYCLETIME or WRCYCLETIME (optimized or not) plus the requested BUSTURNAROUND delay for bus turnaround completion programmed for the chip-select to which the NAND device is connected to.

Alternatively, a round-robin arbitration can be used to prioritize accesses to the external bus. This arbitration scheme is enabled by setting the GPMC.GPMC\_PREFETCH\_CONFIG1[23] PFPWENROUNDROBIN bit. When a request to another chip-select is received while the prefetch and write-posting engine is active, priority is given to the new request. The request processed thereafter is the prefetch and write-posting engine request, even if another interconnect request is passed in the mean time. The engine keeps control of the bus for an additional number of requests programmed in the GPMC.GPMC\_PREFETCH\_CONFIG1[19:16] PFPWWEIGHTEDPRIO bit field. Control is then passed to the direct interconnect request.

As an example, the round-robin arbitration scheme is selected with PFPWWEIGHTEDPRIO set to 0x2. Considering the prefetch and write-posting engine and the interconnect interface are always requesting access to the external interface, the GPMC grants priority to the direct interconnect access for one request. The GPMC then grants priority to the engine for three requests, and finally back to the direct interconnect access, until the arbiter is reset when one of the two initiators stops initiating requests.

## 11.1.6 GPMC Use Cases and Tips

### 11.1.6.1 How to Set GPMC Timing Parameters for Typical Accesses

#### 11.1.6.1.1 External Memory Attached to the GPMC Module

As discussed in the introduction to this chapter, the GPMC module supports the following external memory types:

- Asynchronous or synchronous, 8-bit or 16-bit-width memory or device
- 16-bit address/data-multiplexed or not multiplexed NOR flash device
- 8- or 16-bit NAND flash device

The following examples show how to calculate GPMC timing parameters by showing a typical parameter setup for the access to be performed.

The example is based on a 512-Mb multiplexed NOR flash memory with the following characteristics:

- Type: NOR flash (address/data-multiplexed mode)
- Size: 512M bits
- Data Bus: 16 bits wide
- Speed: 104-MHz clock frequency
- Read access time: 80 ns

#### 11.1.6.1.2 Typical GPMC Setup

[Table 11-17](#) lists some of the I/Os of the GPMC module.

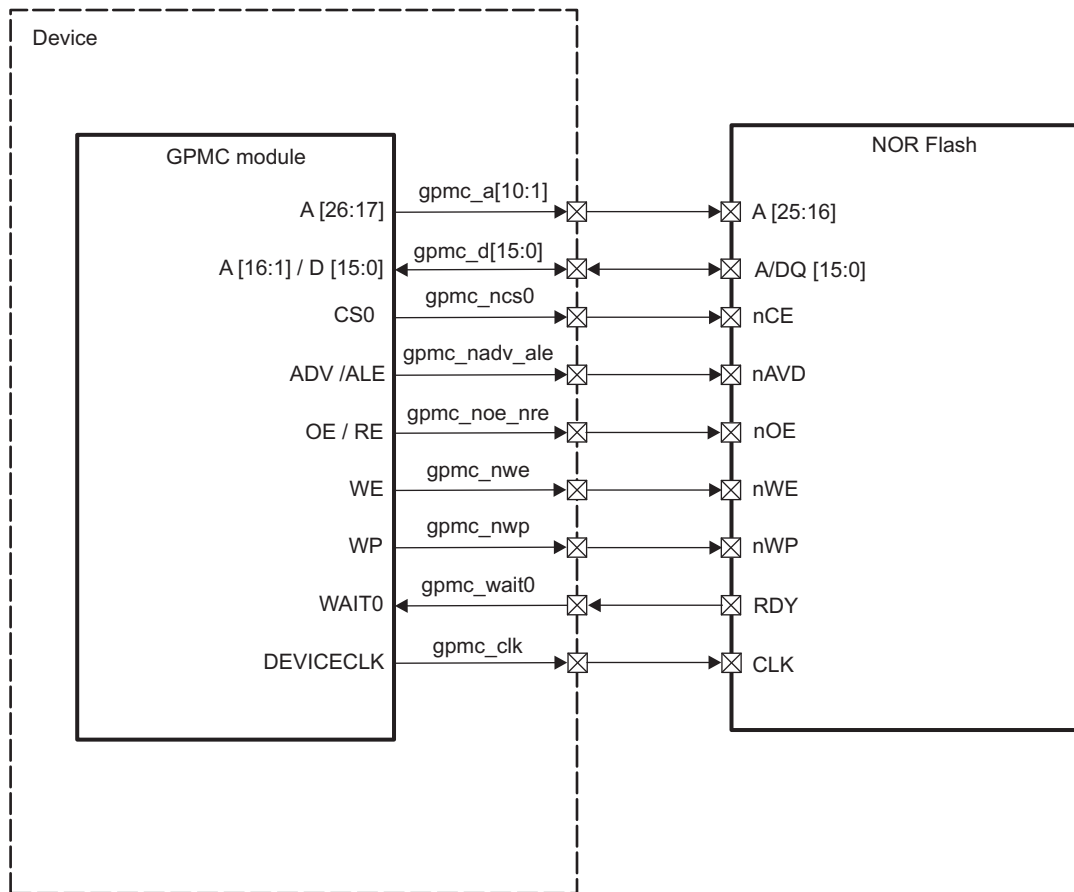

**Table 11-17. GPMC Signals**

Signal Name	I/O	Description
GPMC_FCLK	Internal	Functional and interface clock. Acts as the time reference.
gpmc_clk	I/O	External clock provided to the external device for synchronous operations
gpmc_a[10: 1]	O	Address
gpmc_d[15: 0]	I/O	Data-multiplexed with addresses A[16:1] on memory side
gpmc_ncs	O	Chip-select
gpmc_nadv_ale	O	Address valid enable
gpmc_noe_nre	O	Output enable (read access only)
gpmc_nwe	O	Write enable (write access only)
gpmc_wait[3:0]	I	Ready signal from memory device. Indicates when valid burst data is ready to be read

Figure 11-37 shows the typical connection between the GPMC module and an attached NOR flash memory.

**Figure 11-37. GPMC Connection to an External NOR Flash Memory**

gpmc\_037

The following sections demonstrate how to calculate GPMC parameters for three access types:

- Synchronous burst read
- Asynchronous read
- Asynchronous single write

#### 11.1.6.1.2.1 GPMC Configuration for Synchronous Burst Read Access

The clock runs at 104 MHz ( $f = 104 \text{ MHz}$ ;  $T = 9,615 \text{ ns}$ ).

Table 11-18 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 11-19 shows how to calculate timings for the GPMC using the memory parameters.

Figure 11-38 shows the synchronous burst read access.

**Table 11-18. Useful Timing Parameters on the Memory Side**

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCES	nCS setup time to clock	0
tACS	Address setup time to clock	3
tIACC	Synchronous access time	80

**Table 11-18. Useful Timing Parameters on the Memory Side (continued)**

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tBACC	Burst access time valid clock to output delay	5,2
tCEZ	Chip-select to High-Z	7
tOEZ	Output enable to High-Z	7
tAVC	nADV setup time	6
tAVD	nAVD pulse	6
tACH	Address hold time from clock	3

The following terms, which describe the timing interface between the controller and its attached device, are used to calculate the timing parameters on the GPMC side:

- Read access time (GPMC side): Time required to activate the clock + read access time requested on the memory side + data setup time required for optimal capture of a burst of data
- Data setup time (GPMC side): Ensures a good capture of a burst of data (as opposed to taking a burst of data out). One burst of data is processed in one clock cycle ( $T = 9,615$  ns). The read access time between two bursts of data is  $tBACC = 5,2$  ns. Therefore, data setup time is a clock period -  $tBACC = 4,415$  ns of data setup.
- Access completion (GPMC side): (Different from page burst access time) Time required between the last burst access and access completion: nCS/nOE hold time (nCS and nOE must be released at the end of an access. These signals are held to allow the access to complete).
- Read cycle time (GPMC side): Read access time + access completion
- Write cycle time for burst access: Not supported for NOR flash memory

**Table 11-19. Calculating GPMC Timing Parameters**

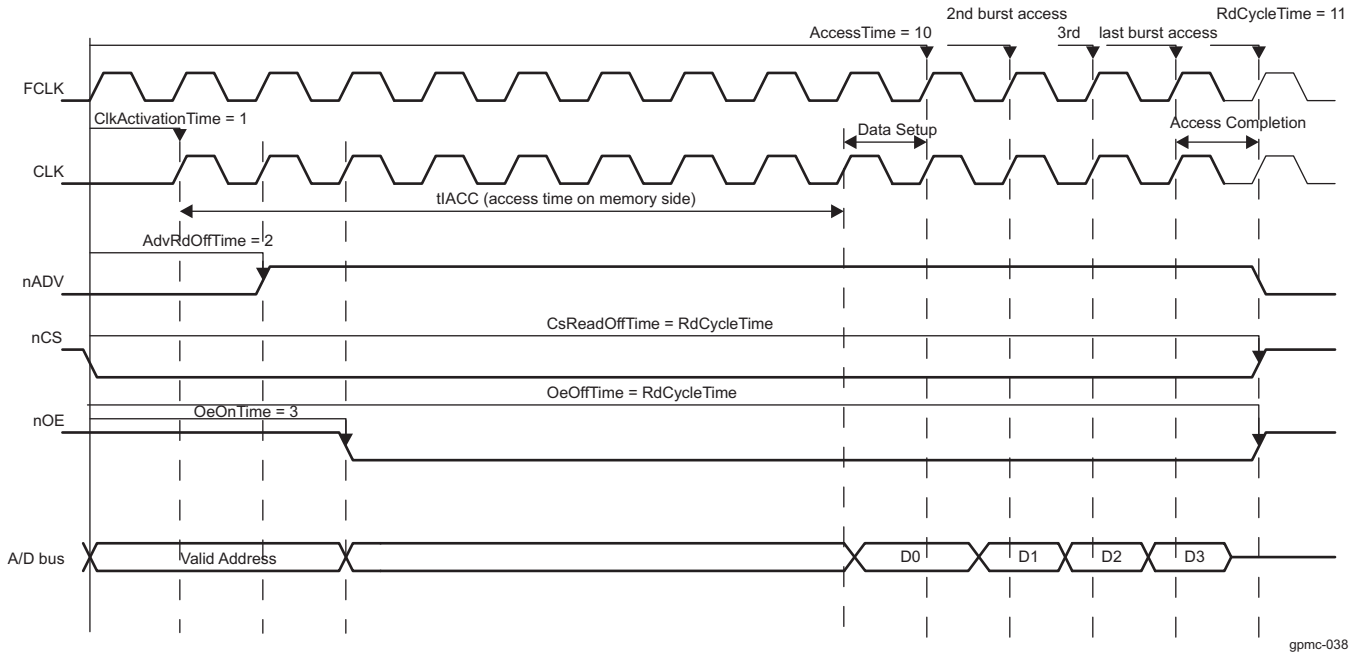

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
ClkActivationTime	$\min (tCES, tACS)$	3	1	CLKACTIVATIONTIME = 0x1
RdAccessTime	$\text{roundmax} (\text{ClkActivationTime} + tIACC + \text{DataSetupTime})$	94,03: (9,615 + 80 + 4,415)	10 : $\text{roundmax} (94,03 / 9,615)$	ACCESSTIME = 0x0A
PageBurstAccessTime	$\text{roundmax} (tBACC)$	$\text{roundmax} (5,2)$	1	PAGEBURSTACCESSTIME = 0x1
RdCycleTime	$\text{AccessTime} + \max (tCEZ, tOEZ)$	101, 03: (94, 03 + 7)	11	RDCYCLETIME = 0x0B
CsOnTime	tCES	0	0	CSONTIME = 0x0
CsReadOffTime	RdCycleTime	-	11	CSRDOFFTIME = 0x0B
AdvOnTime	tAVC <sup>(1)</sup>	0	0	ADVONTIME = 0x0
AdvRdOffTime	tAVD + tAVC <sup>(2)</sup>	12	2	ADVRDOFFTIME = 0x02
OeOnTime <sup>(3)</sup>	$(\text{ClkActivationTime} + tACH) < \text{OeOnTime} < (\text{ClkActivationTime} + tIACC)$	-	3 for instance.	OEONTIME = 0x3
OeOffTime	RdCycleTime	-	11	OEOFFTIME = 0x0B

<sup>(1)</sup> The external clock provided to the NOR flash is not yet available.

<sup>(2)</sup>  $\text{AdvRdOffTime} - \text{AdvOnTime} = tAVD$ ; thus,  $\text{AdvRdOffTime} = tAVD + \text{AdvOnTime} = tAVD + tAVC$ .

<sup>(3)</sup> OeOnTime must guarantee that addresses are available. It must not exceed the availability of the first burst of data.

**Figure 11-38. Synchronous Burst Read Access (Timing Parameters in Clock Cycles)**

**11.1.6.1.2.2 GPMC Configuration for Asynchronous Read Access**

The clock runs at 104 MHz ( f = 104 MHz; T = 9, 615 ns).

Table 11-20 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 11-21 shows how to calculate timings for the GPMC using the memory parameters.

Figure 11-39 shows the asynchronous read access.

**Table 11-20. AC Characteristics for Asynchronous Read Access**

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCE	Read Access time from nCS low	80
tAAVDS	Address setup time to rising edge of nADV	3
tAVDP	nADV low time	6
tCAS	nCS setup time to nADV	0
tOE	Output enable to output valid	6
tOEZ	Output enable to High-Z	7

Use the following formula to calculate the RdCycleTime parameter for this typical access:

$$RdCycleTime = RdAccessTime + AccessCompletion = RdAccessTime + 1 \text{ clock cycle} + tOEZ:$$

- First, on the memory side, the external memory makes the data available to the output bus. This is the memory-side read access time defined in Table 11-20: the number of clock cycles between the address capture (nADV rising edge) and the data valid on the output bus.

The GPMC side requires some hold to allow the data to be captured correctly and the access to be finished.

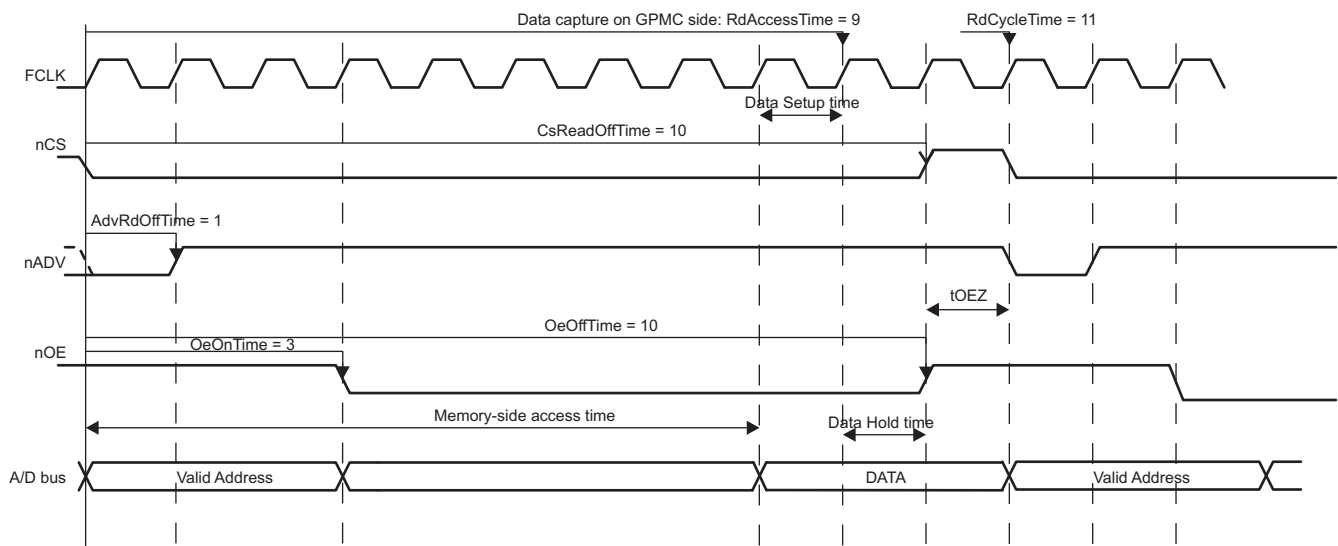

- To read the data correctly, the GPMC must capture it with enough data setup time; the GPMC module captures the data on the next rising edge. This is access time on the GPMC side.
- There must also be a data hold time for correctly reading the data (checking that there is no nOE/nCS deassertion while reading the data). This data hold time is 1 clock cycle (AccessTime + 1).

- To complete the access, nOE/nCS signals are driven to High-Z. AccessTime + 1 + tOEZ is the read cycle time.
- Addresses can now be relatched and a new read cycle begun.

**Table 11-21. GPMC Timing Parameters for Asynchronous Read Access**

Parameter Name on GPMC side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
ClkActivationTime		n/a (asynchronous mode)		
AccessTime	round max (tCE)	80	9	ACCESSTIME = 0x09
PageBurstAccess Time	n/a (single access)			
RdCycleTime	AccessTime + 1 cycle + tOEZ	96, 615	11	RDCYCLETIME = 0x0B
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsReadOffTime	AccessTime + 1 cycle	89, 615	10	CSRDOFFTIME = 0x0A
AdvOnTime	tAAVDS	3	1	ADVONTIME = 0x1
AdvRdOffTime	tAAVDS + tAVDP	9	1	ADVRDOFFTIME = 0x01
OeOnTime	OeOnTime >= AdvRdOffTime (multiplexed mode)	-	3 for instance	OEONTIME = 0x3
OeOffTime	AccessTime + 1 cycle	89, 615	10	OEOFFTIME = 0x0A

**Figure 11-39. Asynchronous Single Read Access (Timing Parameters in Clock Cycles)**

gpmc-039

### 11.1.6.1.2.3 GPMC Configuration for Asynchronous Single Write Access

The clock runs at 104 MHz: (f = 104 MHz; T = 9, 615 ns).

Table 11-23 shows how to calculate timings for the GPMC using the memory parameters.

Table 11-22 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Figure 11-40 shows the synchronous burst write access.

**Table 11-22. AC Characteristics for Asynchronous Single Write ( Memory Side)**

AC Characteristics on the Memory Side	Description	Duration (ns)
tWC	Write cycle time	60
tAVDP	nADV low time	6
tWP	Write pulse width	25
tWPH	Write pulse width high	20
tCS	nCS setup time to nWE	3
tCAS	nCS setup time to nADV	0
tAVSC	nADV setup time	3

For asynchronous single write access, write cycle time is  $WrCycleTime = WeOffTime + AccessCompletion = WeOffTime + 1$ . For the AccessCompletion: 1 cycle is required for data hold time (nCS deassertion).

**Table 11-23. GPMC Timing parameters for Asynchronous Single Write**

Parameter Name on GPMC side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Registers Configuration
ClkActivationTime		n/a (asynchronous mode)		
AccessTime	Applicable only to WAITMONITORING (the value is the same as for read access)			
PageBurstAccessTime		n/a (single access)		
WrCycleTime	$WeOffTime + AccessCompletion$	57, 615	6	WRCYCLETIME = 0x06
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsWrOffTime	$WeOffTime + 1$	57, 615	6	CSWROFFTIME = 0x06
AdvOnTime	tAVSC	3	1	ADVONTIME = 0x1
AdvWrOffTime	$tAVSC + tAVDP$	9	1	ADVWROFFTIME = 0x01
WeOnTime	tCS	3	1	WEONTIME = 0x1
WeOffTime	$tCS + tWP + tWPH$	48	5	WEOFFTIME = 0x05

**Figure 11-40. Asynchronous Single Write Access (Timing Parameters in Clock Cycles)**

gpmc-040

### 11.1.6.2 How to Choose a Suitable Memory to Use With the GPMC

This section explains how to select a suitable memory device to interface with the GPMC controller.

#### 11.1.6.2.1 Supported Memories or Devices

NAND flash and NOR flash architectures are the two flash technologies. The GPMC supports various types of external memory or device, basically any one that supports NAND or NOR protocols:

- 8- and 16-bit width asynchronous or synchronous memory or device (8-bit: non burst device only)
- 16-bit address and data multiplexed NOR flash devices (pSRAM, OneNAND™, ...)
- 8- and 16-bit NAND flash device

---

**NOTE:** Nonmultiplexed NOR flash devices are supported by the GPMC, but their use is highly limited. Because only ten address pins are available on the GPMC interface, the maximum device size supported is 2KB.

---

##### 11.1.6.2.1.1 Memory Pin Multiplexing

This section describes the interfacing differences of the supported GPMC memories.

**Table 11-24. Supported Memory Interfaces**

Function	16-Bit Address/Data Muxed pSRAM or NOR Flash <sup>(1)</sup>	OneNAND	16-bit NAND	8-bit NAND
gpmc_a10	A26			
gpmc_a9	A25			
gpmc_a8	A24			
gpmc_a7	A23			
gpmc_a6	A22			
gpmc_a5	A21			
gpmc_a4	A20			
gpmc_a3	A19			
gpmc_a2	A18			
gpmc_a1	A17			
gpmc_d15	D15 or A16		IO15	
gpmc_d14	D14 or A15		IO14

gpmc_wait2	WAIT2		R/nB2	
gpmc_wait3	WAIT3		R/nB3	

### 11.1.6.2.1.2 NAND Interface Protocol

NAND flash architecture, introduced in 1989, is a flash technology. NAND is a page-oriented memory device (that is, read and write accesses are done by pages). NAND achieves density by sharing common areas of the storage transistor, which creates strings of serially connected transistors (in NOR devices, each transistor stands alone). Because of its high density, NAND is best suited to devices requiring high capacity data storage, such as pictures, music, or data files. Because of its nonvolatility, NAND is a good storage solution for many applications where mobility, low power, and speed are key factors. Low pin count and simple interface are other advantages of NAND.

Table 11-25 summarizes the level of the NAND interface signals applied to external devices or memories.

**Table 11-25. NAND Interface Bus Operations Summary**

Bus operation	CLE	ALE	nCE	nWE <sup>(1)</sup>	nRE <sup>(1)</sup>	nWP
Read (cmd input)	H	L	L	RE	H	x
Read (add input)	L	H	L	RE	H	x
Write (cmd input)	H	L	L	RE	H	H
Write (add input)	L	H	L	RE	H	H
Data input	L	L	L	RE	H	H
Data output	L	L	L	H	FE	x
Busy (during read)	x	x	H <sup>(2)</sup>	H <sup>(2)</sup>	H <sup>(2)</sup>	x
Busy (during program)	x	x	x	x	x	H
Busy (during erase)	x	x	x	x	x	H
Write protect	x	x	x	x	x	L
Stand-by	x	x	H	x	x	H/L <sup>(3)</sup>

<sup>(1)</sup> RE stands for rising edge, FE stands for falling edge.

<sup>(2)</sup> Can be either nCE high, or WE and nRE high

<sup>(3)</sup> nWP must be biased to CMOS high or CMOS low for standby.

### 11.1.6.2.1.3 NOR Interface Protocol

NOR flash architecture, introduced in 1988, is a flash technology. Unlike NAND, which is a sequential access device, NOR is directly addressable (that is, it is designed to be a random access device). NOR is best suited to devices used to store and run code or firmware, usually in small capacities. While NOR has fast read capabilities, it has slow write and erase functions compared to NAND architecture.

Table 11-26 summarizes the level of the NOR interface signals applied to external devices or memories.

**Table 11-26. NOR Interface Bus Operations Summary**

Bus operation	CLK	nADV	nCS	nOE	nWE	WAIT	DQ[15:0]
Read (asynchronous)	x	L	L	L	H	Asserted	Output
Read (synchronous)	Running	L	L	L	H	Driven	Output
Read (burst suspend)	Halted	x	L	H	H	Active	Output
Write	x	L	L	H	L	Asserted	Input
Output disable	x	x	L	H	H	Asserted	High-Z
Standby	x	x	H	x	x	High-Z	High-Z

### 11.1.6.2.1.4 Other Technologies

Other supported device types interact with the GPMC through the NOR interface protocol.

OneNAND is a high density and low-power memory device. OneNAND is based on a single- or multilevel-cell NAND core with SRAM and logic, and interfaces as a synchronous NOR flash; it also has synchronous write capability. It reads faster than conventional NAND and writes faster than conventional NOR flash. Therefore, it is appropriate for both mass storage and code storage.

pSRAM is a low-power memory device for mobile applications. pSRAM is based on the DRAM cell with internal refresh and address control features, and interfaces as a synchronous NOR flash; it also has synchronous write capability.

### 11.1.6.2.1.5 Supported Protocols

The GPMC supports the following interface protocols when communicating with external memory or external devices:

- Asynchronous read/write access
- Asynchronous read page access (4-8-16 Word16)
- Synchronous read/write access
- Synchronous read burst access without wrap capability (4-8-16 Word16)
- Synchronous read burst access with wrap capability (4-8-16 Word16)

### 11.1.6.2.2 GPMC Features and Settings

This section lists the GPMC features and settings:

- Supported device type: up to eight NAND or NOR protocol external memories or devices
- Operating voltage: 1.8 V
- Maximum operating frequency provided externally: up to 100 MHz (single device) with an L3-clock of 100 MHz. Up to 83 MHz (L3-clock divided by two) with an L3-clock of 166 MHz.
- Maximum GPMC addressing capability: 1 GB divided into eight chip-selects
- Maximum supported memory size: 128 MB (must be a power-of-2)
- Minimum supported memory size: 16 MB (must be a power-of-2). Aliasing occurs when addressing smaller memories.
- Data path to external memory or device: 8- and 16-bit wide
- Burst and page access: burst of 4-8-16 Word16
- Supports bus keeping and bus turnaround

## 11.1.7 GPMC Register Manual

### 11.1.7.1 GPMC Instance Summary

Table 11-27 describes the GPMC instance.

**Table 11-27. GPMC Instance Summary**

Module Name	Base Address	Size
GPMC	0x6E00 0000	16 MB

### 11.1.7.2 GPMC Register Summary

Table 11-28 is a summary of the GPMC registers.

**Table 11-28. GPMC Registers Mapping Summary**

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address
GPMC_REVISION	R	32	0x0000 0000	0x6E00 0000
GPMC_SYSCONFIG	RW	32	0x0000 0010	0x6E00 0010
GPMC_SYSSTATUS	R	32	0x0000 0014	0x6E00 0014
GPMC_IRQSTATUS	RW	32	0x0000 0018	0x6E00 0018

### 11.1.7.3 GPMC Register Description

This section provides a description of GPMC registers.

**NOTE:** All GPMC registers are aligned to 32-bit address boundaries. All register file accesses, except to [GPMC\\_NAND\\_DATA\\_i](#) register, are little endian. If the [GPMC\\_NAND\\_DATA\\_i](#) register location is accessed, the endianness is access-dependent.

**Table 11-29. GPMC\_REVISION**

<b>Address Offset</b>	0x0000 0000	
<b>Physical Address</b>	0x6E00 0000	<b>Instance</b> GPMC
<b>Description</b>	This register contains the IP revision code.	
<b>Type</b>	R	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																REV															

Bits	Field Name	Description	Type	Reset
31:8	Reserved	Reads return 0.	R	0x000000
7:0	REV	IP revision [7:4] Major revision [3:0] Minor revision Examples: 0x10 for 1.0, 0x21 for 2.1	R	See <sup>(1)</sup>

<sup>(1)</sup> TI internal data

**Table 11-30. Register Call Summary for Register GPMC\_REVISION**

General-Purpose Memory Controller

- [GPMC Register Summary: \[0\]](#)

**Table 11-31. GPMC\_SYSCONFIG**

<b>Address Offset</b>	0x0000 0010	
<b>Physical Address</b>	0x6E00 0010	<b>Instance</b> GPMC
<b>Description</b>	This register controls the various parameters of the Interconnect.	
<b>Type</b>	RW	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																IDLEMODE	RESERVED	SOFTRESET	AUTOIDLE												

Bits	Field Name	Description	Type	Reset
31:5	RESERVED	Write 0s for future compatibility. Reads return 0s.	RW	0x00000000
4:3	IDLEMODE	0x0: Force-idle. An idle request is acknowledged unconditionally 0x1: No-idle. An idle request is never acknowledged 0x2: Smart-idle. Acknowledgment to an idle request is given based on the internal activity of the module 0x3: Do not use	RW	0x0
2	RESERVED	Write 0 for future compatibility Reads returns 0	RW	0x0

Bits	Field Name	Description	Type	Reset
1	SOFTRESET	Software reset. Set this bit to 1 triggers a module reset. This bit is automatically reset by hardware. During reads, it always returns 0.  0x0: Normal mode 0x1: The module is reset	RW	0x0
0	AUTOIDLE	Internal Interface clock gating strategy  0x0: Interface clock is free-running 0x1: Automatic Interface clock gating strategy is applied, based on the Interconnect activity	RW	0x0

**Table 11-35. GPMC\_IRQSTATUS**

<b>Address Offset</b>	0x0000 0018	<b>Instance</b>	GPMC
<b>Physical Address</b>	0x6E00 0018		
<b>Description</b>	This interrupt status register regroups all the status of the module internal events that can generate an interrupt.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0								
RESERVED																WAIT3EDGEDETECTIONSTATUS				WAIT2EDGEDETECTIONSTATUS				WAIT1EDGEDETECTIONSTATUS				WAIT0EDGEDETECTIONSTATUS				RESERVED				TERMINALCOUNTSTATUS		FIFOEVENTSTATUS	

Bits	Field Name	Description	Type	Reset
31:12	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00000
11	WAIT3EDGEDETECTIONSTATUS	Status of the Wait3 Edge Detection interrupt Read 0x0: A transition on WAIT3 input pin has not been detected Write 0x0: WAIT3EDGEDETECTIONSTATUS bit unchanged Read 0x1: A transition on WAIT3 input pin has been detected Write 0x1: WAIT3EDGEDETECTIONSTATUS bit is reset	RW	0x0
10	WAIT2EDGEDETECTIONSTATUS	Status of the Wait2 Edge Detection interrupt Read 0x0: A transition on WAIT2 input pin has not been detected Write 0x0: WAIT2EDGEDETECTIONSTATUS bit unchanged Read 0x1: A transition on WAIT2 input pin has been detected Write 0x1: WAIT2EDGEDETECTIONSTATUS bit is reset	RW	0x0
9	WAIT1EDGEDETECTIONSTATUS	Status of the Wait1 Edge Detection interrupt Read 0x0: A transition on WAIT1 input pin has not been detected Write 0x0: WAIT1EDGEDETECTIONSTATUS bit unchanged Read 0x1: A transition on WAIT1 input pin has been detected Write 0x1: WAIT1EDGEDETECTIONSTATUS bit is reset	RW	0x0
8	WAIT0EDGEDETECTIONSTATUS	Status of the Wait0 Edge Detection interrupt Read 0x0: A transition on WAIT0 input pin has not been detected Write 0x0: WAIT0EDGEDETECTIONSTATUS bit unchanged Read 0x1: A transition on WAIT0 input pin has been detected Write 0x1: WAIT0EDGEDETECTIONSTATUS bit is reset	RW	0x0
7:2	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00
1	TERMINALCOUNTSTATUS	Status of the TerminalCountEvent interrupt Read 0x0: Indicates that CountValue is greater than 0 Write 0x0: TERMINALCOUNTSTATUS bit unchanged Read 0x1: Indicates that CountValue is equal to 0 Write 0x1: TERMINALCOUNTSTATUS bit is reset	RW	0x0

Bits	Field Name	Description	Type	Reset
0	FIFOEVENTSTATUS	Status of the FIFOEvent interrupt  Read 0x0: Indicates than less than FIFOThreshold bytes are available in prefetch mode and less than FIFOThreshold bytes free places are available in write-posting mode.  Write 0x0: FIFOEVENTSTATUS bit unchanged  Read 0x1: Indicates than at least FIFOThreshold bytes are available in prefetch mode and at least FIFOThreshold bytes free places are available in write-posting mode.  Write 0x1: FIFOEVENTSTATUS bit is reset	RW	0x0

**Table 11-37. GPMC\_IRQENABLE**

<b>Address Offset</b>	0x0000 001C	<b>Instance</b>	GPMC
<b>Physical Address</b>	0x6E00 001C		
<b>Description</b>	The interrupt enable register allows to mask/unmask the module internal sources of interrupt, on a event-by-event basis.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																WAIT3EDGEDETECTIONENABLE				RESERVED				TERMINALCOUNTEVENTENABLE		FIFOEVENTENABLE					

Bits	Field Name	Description	Type	Reset
31:12	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00000
11	WAIT3EDGEDETECTION ENABLE	Enables the Wait3 Edge Detection interrupt  0x0: Wait3EdgeDetection interrupt is masked  0x1: Wait3EdgeDetection event generates an interrupt if occurs	RW	0x0
10	WAIT2EDGEDETECTION ENABLE	Enables the Wait2 Edge Detection interrupt  0x0: Wait2EdgeDetection interrupt is masked  0x1: Wait2EdgeDetection event generates an interrupt if occurs	RW	0x0
9	WAIT1EDGEDETECTION ENABLE	Enables the Wait1 Edge Detection interrupt  0x0: Wait1EdgeDetection interrupt is masked  0x1: Wait1EdgeDetection event generates an interrupt if occurs	RW	0x0
8	WAIT0EDGEDETECTION ENABLE	Enables the Wait0 Edge Detection interrupt  0x0: Wait0EdgeDetection interrupt is masked  0x1: Wait0EdgeDetection event generates an interrupt if occurs	RW	0x0
7:2	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00

Bits	Field Name	Description	Type	Reset
1	TERMINALCOUNTEVENT ENABLE	Enables TerminalCountEvent interrupt issuing in pre-fetch or write-posting mode  0x0: TerminalCountEvent interrupt is masked 0x1: TerminalCountEvent interrupt is not masked	RW	0x0
0	FIFOEVENTENABLE	Enables the FIFOEvent interrupt  0x0: FIFOEvent interrupt is masked 0x1: FIFOEvent interrupt is not masked	RW	0x0

Bits	Field Name	Description	Type	Reset
31	WRAPBURST	Enables the wrapping burst capability. Must be set if the attached device is configured in wrapping burst 0x0: Synchronous wrapping burst not supported 0x1: Synchronous wrapping burst supported	RW	0x0
30	READMULTIPLE	Selects the read single or multiple access 0x0: Single access 0x1: Multiple access (burst if synchronous, page if asynchronous)	RW	0x0
29	READTYPE	Selects the read mode operation 0x0: Read Asynchronous 0x1: Read Synchronous	RW	0x0

Bits	Field Name	Description	Type	Reset
28	WRITEMULTIPLE	Selects the write single or multiple access 0x0: Single access 0x1: Multiple access (burst if synchronous, considered as single if asynchronous)	RW	0x0
27	WRITETYPE	Selects the write mode operation 0x0: Write Asynchronous 0x1: Write Synchronous	RW	0x0
26:25	CLKACTIVATIONTIME	Output GPMC_CLK activation time 0x0: First rising edge of GPMC_CLK at start access time 0x1: First rising edge of GPMC_CLK one GPMC_FCLK cycle after start access time 0x2: First rising edge of GPMC_CLK two GPMC_FCLK cycles after start access time 0x3: Reserved	RW	0x0
24:23	ATTACHEDDEVICEPAGE LENGTH	Specifies the attached device page (burst) length 0x0: 4 Words 0x1: 8 Words 0x2: 16 Words 0x3: Reserved (1 Word = Interface size)	RW	0x0
22	WAITREADMONITORING	Selects the Wait monitoring configuration for Read accesses (Reset value is BOOTWAITEN input pin sampled at IC reset) 0x0: Wait pin is not monitored for read accesses 0x1: Wait pin is monitored for read accesses	RW	0x-
21	WAITWRITEMONITORING	Selects the Wait monitoring configuration for Write accesses 0x0: Wait pin is not monitored for write accesses 0x1: Wait pin is monitored for write accesses	RW	0x0
20	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0
19:18	WAITMONITORINGTIME	Selects input pin Wait monitoring time 0x0: Wait pin is monitored with valid data 0x1: Wait pin is monitored one GPMC_CLK cycle before valid data 0x2: Wait pin is monitored two GPMC_CLK cycle before valid data 0x3: Reserved	RW	0x0
17:16	WAITPINSELECT	Selects the input WAIT pin for this chip-select (Reset value is BOOTWAITSELECT input pin sampled at IC reset for CS0 and 0 for CS1-7) 0x0: Wait input pin is WAIT0 0x1: Wait input pin is WAIT1 0x2: Wait input pin is WAIT2 0x3: Wait input pin is WAIT3	RW	0x-
15:14	RESERVED	Write 0s for future compatibility. Reads returns 0	RW	0x0
13:12	DEVICESTYPE	Selects the device size attached (Reset value is BOOTDEVICESTYPE input pin sampled at IC reset for CS0 and 0x1 for CS1 to CS7) 0x0: 8 bit 0x1: 16 bit 0x2: Reserved 0x3: Reserved	RW	0x-

Bits	Field Name	Description	Type	Reset
11:10	DEVICETYPE	Selects the attached device type 0x0: NOR Flash like, asynchronous and synchronous devices 0x1: Reserved 0x2: NAND Flash like devices, stream mode 0x3: Reserved	RW	0x0
9	MUXADDDATA	Enables the Address and data multiplexed protocol (Reset value is CS0MUXDEVICE input pin sampled at IC reset for CS0 and 0 for CS1-7) 0x0: Non Multiplexed attached device 0x1: Address and data multiplexed attached device	RW	0x-
8:5	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
4	TIMEPARAGRANULARITY	Signals timing latencies scalar factor (Rd/WrCycleTime, Rd/WrAccessTime, PageBurstAccessTime, CSOnTime, CSRd/WrOffTime, ADVOnTime, ADVRd/WrOffTime, OEOnTime, OEOffTime, WEOnTime, WEOffTime, Cycle2CycleDelay, BusTurnAround, TimeOutStartValue) 0x0: x1 latencies 0x1: x2 latencies	RW	0x0
3:2	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
1:0	GPMC_FCLKDIVIDER	Divides the GPMC_FCLK clock 0x0: GPMC_CLK frequency = GPMC_FCLK frequency 0x1: GPMC_CLK frequency = GPMC_FCLK frequency / 2 0x2: GPMC_CLK frequency = GPMC_FCLK frequency / 3 0x3: GPMC_CLK frequency = GPMC_FCLK frequency / 4	RW	0x0

Bits	Field Name	Description	Type	Reset
31	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0
30:28	CYCLEOPTIMIZATION	Define the number of GPMC_FCLK cycles to be subtracted from RdCycleTime, WrCycleTime, AccessTime, CSRdOffTime, CSWrOffTime, ADVRdOffTime, ADVWrOffTime, OEOffTime, WEOffTime 0x0: 0 GPMC_FCLK cycle 0x1: 1 GPMC_FCLK cycle ... 0x7: 7 GPMC_FCLK cycles	RW	0x0
27	ENABLEOPTIMIZEDACCESS	Enables access cycle optimization 0x0: Access cycle optimization is disabled 0x1: Access cycle optimization is enabled	RW	0x0
26:24	ENGINECSSELECTOR	Selects the CS where Prefetch Postwrite engine is active 0x0 corresponds to CS0 0x1: CS1 ... 0x7: CS7	RW	0x0
23	PPFWENROUNDROBIN	Enables the PFPW RoundRobin arbitration 0x0: Prefetch Postwrite engine round robin arbitration is disabled 0x1: Prefetch Postwrite engine round robin arbitration is enabled	RW	0x0
22:20	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
19:16	PPFWWEIGHTEDPRIO	When an arbitration occurs between a DMA and a PFPW engine access, the DMA is always serviced. If the PFPWEnRoundRobin is enabled, 0x0: the next access is granted to the PFPW engine, 0x1: the two next accesses are granted to the PFPW engine, ..., 0xF: the 16 next accesses are granted to the PFPW engine.	RW	0x0
15	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0
14:8	FIFOTHRESHOLD	Selects the maximum number of bytes read from the FIFO or written to the FIFO by the host on a DMA or interrupt request 0x00: 0 byte 0x01: 1 byte ... 0x40: 64 bytes	RW	0x40
7	ENABLEENGINE	Enables the Prefetch Postwrite engine 0x0: Prefetch Postwrite engine is disabled 0x1: Prefetch Postwrite engine is enabled	RW	0x0
6	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0
5:4	WAITPINSELECTOR	Select which wait pin edge detector should start the engine in synchronized mode 0x0: Selects Wait0EdgeDetection 0x1: Selects Wait1EdgeDetection 0x2: Selects Wait2EdgeDetection 0x3: Selects Wait3EdgeDetection	RW	0x0
3	SYNCHROMODE	Selects when the engine starts the access to CS 0x0: Engine starts the access to CS as soon as STARTENGINE is set  0x1: Engine starts the access to CS as soon as STARTENGINE is set AND wait to non wait edge detection on the selected wait pin	RW	0x0

Bits	Field Name	Description	Type	Reset
2	DMAMODE	Selects interrupt synchronization or DMA request synchronization  0x0: Interrupt synchronization is enabled. Only interrupt line will be activated on FIFO threshold crossing.  0x1: DMA request synchronization is enabled. A DMA request protocol is used.	RW	0x0
1	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0
0	ACCESSMODE	Selects pre-fetch read or write-posting accesses  0x0: Pre-fetch read mode  0x1: Write-posting mode	RW	0x0

## 11.2 SDRAM Controller (SDRC) Subsystem

This section describes the SDRAM controller (SDRC) subsystem.

### 11.2.1 SDRC Subsystem Overview

The SDRC subsystem module provides connectivity between the OMAP™ device and external discrete, stacked or POP-ed SDRAM memory components. The module includes support for low-power or mobile single-data-rate (LPDDR or M-SDR) and low-power double-data-rate SDRAM (LPDDR).

The SDRC subsystem provides a high-performance interface to a variety of fast memory devices. It comprises two submodules:

- The SDRAM memory scheduler (SMS), consisting of scheduler and virtual rotated frame-buffer (VRFB) modules
- The SDRC

#### CAUTION

DDR SDRAM and SDR SDRAM memory types cannot be connected simultaneously to the SDRC memory interface.

[Figure 11-41](#) shows the SDRC subsystem environment.

**Figure 11-41. SDRC Subsystem Environment**

sdrc-001

### 11.2.1.1 Features

The main features of the SDRC subsystem module are:

- VRFB module
  - Minimizes SDRAM page-miss penalty when accessing graphics buffer in nonnatural raster-scan order
  - Supports rotations of 0, 90, 180, and 270 degrees
  - Transparent to software applications
  - 12 concurrent rotation contexts
- Memory-access scheduler
  - Optimizes latency and bandwidth usage between initiators
  - Per-system initiator group quality-of-service (QoS) control
  - 8 × 8 × 64 request queue FIFO for optimal scheduling
  - Programmable arbitration scheme
  - Focus on real-time memory processes (LCD display, camera interface)

- Focus on MPU/DSP memory latency
- Fair arbitration between other system initiators (DMAs, video subsystem, GFX accelerator)
- Exclusive read-write transaction support
- SDRAM Controller
  - Support for two independent CSs, with their corresponding register sets, and independent page tracking
  - Supports the following memory types:
    - Mobile Single Data Rate SDRAM (M-SDR)
    - Low-Power Double Data Rate SDRAM (LPDDR)
  - Memory device capacity:
    - 16 Mbits, 32 Mbits, 64 Mbits, 128 Mbits, 256 Mbits, 512 Mbits, 1 Gbit, 2 Gbits, and 4 Gbits device support
  - Memory device organization
    - 2-bank support for 16 Mbits and 32 Mbits
    - 4-bank support for 64 Mbits to 4 Gbits
    - Flexible row/column address multiplexing schemes
    - Bank linear addressing
    - 16- or 32-bit data path to external SDRAM memory
    - 1G byte maximum addressing capability
    - Device driver strength feature for mobile DDR supported
    - New flexible address-muxing scheme lets users choose different bank mapping allocations by configuring the bank and column address decoding ordering.
  - Fully pipelined operation for optimal memory bandwidth usage
  - Burst support
    - Memory burst support
      - System burst for SDR SDRAM: system burst translated into memory burst of 2
      - System burst for mobile DDR SDRAM: system burst translated into memory burst size of 4
      - Read interrupt by read, write interrupt by write
  - CAS latency support 1, 2, 3, 4, 5
  - Fully programmable ac timing parameters (on a per-parameter basis). Parameters are set according to the memory interface clock frequency with respect to the attached memory device timing specifications.
  - Fine tuning of the controlled delay elements when operating with DDR memory
  - Dynamic endianness support
  - 9 x 64 bit lookahead FIFO in the SDRAM controller with a maximum of four transaction entries
  - Low-power management support
    - Dynamic power-saving features (internal clock gating)
    - Static power-saving features
    - Support for all standard low-power memory features
    - Support for enhanced low-power features (mobile devices)
    - Very low-power controlled-delay technology for optimal performance with DDR memory
    - Can operate with mobile DDR memory at very low clock rates
  - Autorefresh and self-refresh management

---

**NOTE:** The OMAP device does not support regular devices, SDR or DDR, because of electrical incompatibility.

---

## 11.2.2 SDRC Subsystem Environment

### 11.2.2.1 SDRC Subsystem Description

Figure 11-42 shows the SDRC subsystem interfacing with one 16- and one 32-bit SDR external memories. Figure 11-43 shows the SDRC subsystem interfacing with one 16- and one 32-bit DDR memories.

Figure 11-42. SDRC Subsystem Connections to SDR SDRAM

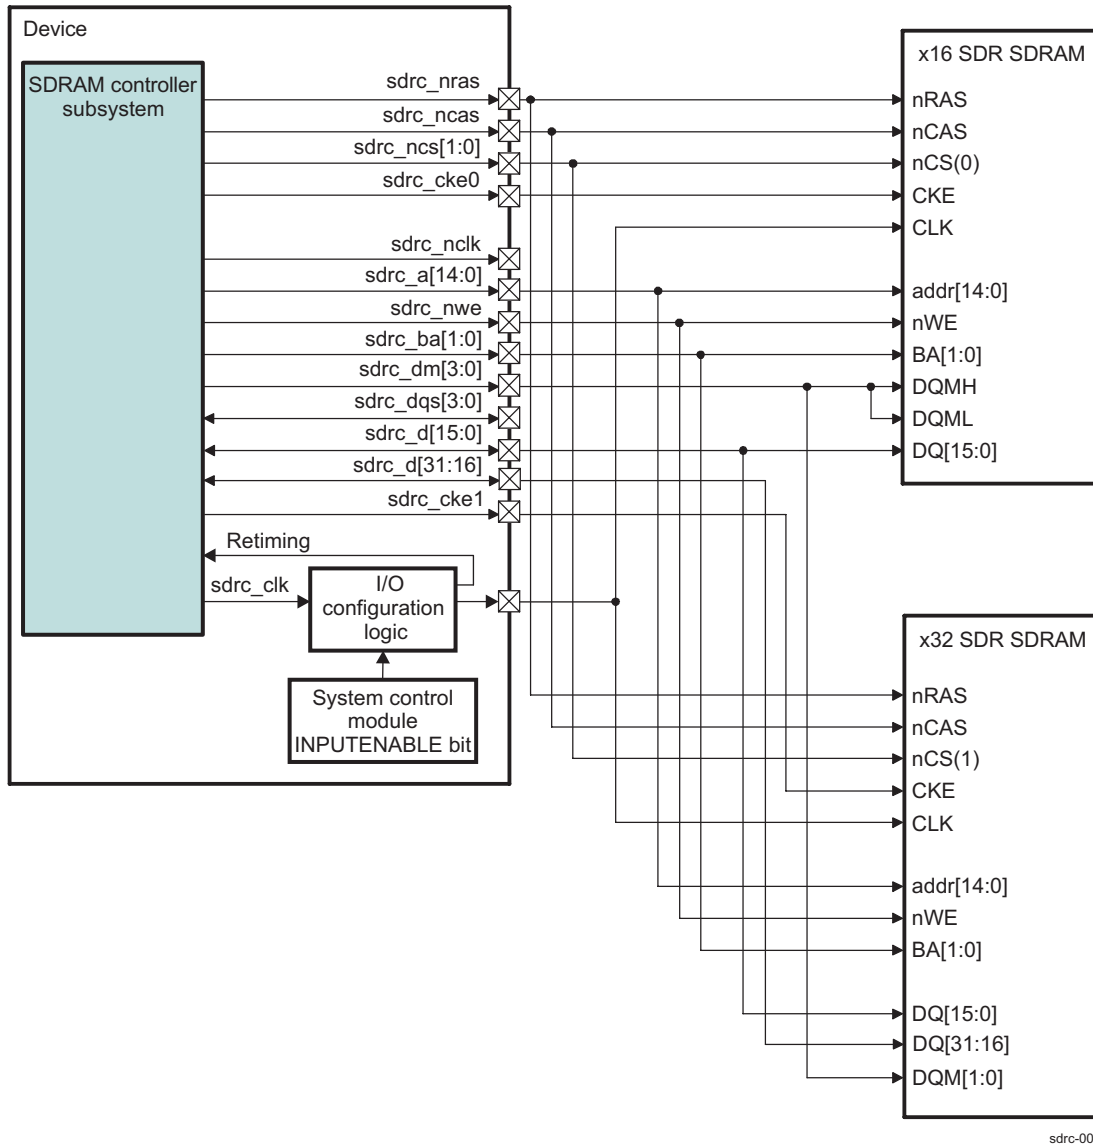

Figure 11-43. SDRC Subsystem Connections to DDR SDRAM

sdr-003

**CAUTION**

Both memory types (SRD/DDR SDRAM) cannot be connected simultaneously to the SDRC memory interface.

Table 11-95 lists SDRC subsystem I/O pins.

**Table 11-95. SDRC Subsystem I/O Description**

Pin	Type	Description
sdrc_d[31:0]	I/O	32-bit wide data bus
sdrc_ba[1:0]	O	Bank address 1-0
sdrc_a[14:0]	O	Address bus
sdrc_ncs[1:0]	O	Chip-select 1-0 (active low)
sdrc_clk	O	Clock <sup>(1)</sup>
sdrc_nclk	O	Clock invert (DDR only)
sdrc_cke0	O	Clock enable (CS0)
sdrc_cke1	O	Clock enable (CS1)
sdrc_nras	O	Row address strobe (active low)
sdrc_ncas	O	Column address strobe (active low)
sdrc_nwe	O	Write enable (active low)
sdrc_dm[3:0]	O	Data mask/OE for SDR read operation
sdrc_dqs[3:0]	I/O	Data output strobe (DDR only)

<sup>(1)</sup> This output signal is also used as retiming input (the CONTROL\_PADCONF\_x.INPUTENABLE bit must be set to 1).

### 11.2.2.2 External Interface Configuration

#### 11.2.2.2.1 CS0, CS1 Memory Spaces

The SDRC can be connected independently to two external SDRAM memories.

Mobile SDR SDRAM memory is supported in sizes of 16 Mbits, 32 Mbits, 64 Mbits, 128 Mbits, 256 Mbits, 512 Mbits, 1 Gbit, 2 Gbits, and 4 Gbits. See [Section 11.2.4.4.1](#) for more information on CS memory spaces.

---

**NOTE:** The OMAP device does not support regular devices, SDR or DDR (see [Section 11.2.5.3.5.1, Chip-Select Configuration](#)).

---

#### 11.2.2.2.2 AC Timing Control

The SDRC permits the configuration of many of the ac timing parameters controlling the SDRAM transaction timing.

It is required to adapt the transaction timing parameters to any memory device attached to the SDRC.

A totally independent, complete set of parameters exists for each CS. The ac parameters and their quantification are summarized in [Section 11.2.5.3.1, Chip-Select Configuration](#).

### 11.2.2.2.3 Address Multiplexing

A flexible address scheme has been added to support any new type of address scheme and SDRAM density. This new address-muxing scheme lets users choose a different bank mapping allocation by configuring the order of the bank and row address decoding (column address always remains the same). The SDRC.SDRC\_MCFG\_p[7:6] BANKALLOCATION field defines the order of the bank and row decoding of the incoming system address. The BANKALLOCATION field can be set on a CS basis. For more details about the flexible address scheme, see [Section 11.2.4.4.3, Address Multiplexing](#).

The programming model is compatible with the legacy fixed address scheme and with the new flexible address scheme. This section describes the fixed address multiplexing configurations for both SDRAM components.

The legacy fixed address scheme is selected when the SDRC.SDRC\_MCFG\_p[19] ADDRMUXLEGACY bit is set to 0 (where p = 0 or 1 for SDRC CS0 or CS1). The fixed address multiplexing configurations are described in this section, for both SDRAM components. An address multiplexing scheme is chosen by programming the SDRC.SDRC\_MCFG\_p[24:20] ADDRMUX field of the SDRC\_MEMCFG registers on a per chip select basis (p = 0 or 1 for CS0 or CS1). [Table 11-96](#) and [Table 11-97](#) show all predefined address multiplexing schemes for SDRAM memory components.

**Table 11-96. SDRC Address Multiplexing Scheme Selection vs SDRAM Configurations (x16 Memory Interface)**

x16 Memory Interface									
Banks		Column Address		Row Address		MUX Scheme	Total Size (Mbits)	Number of Devices	Device Organization

**11.2.3 SDRC Subsystem Integration**

Figure 11-47 shows how the SMS and SDRC modules are integrated into the OMAP device and how they interact with the PRCM module.

**Figure 11-47. SDRC Integration to the OMAP Device**

sdr-007

### 11.2.3.1 Clocking, Reset, and Power Management Scheme

#### 11.2.3.1.1 Clocking

##### 11.2.3.1.1.1 SMS

The SMS is a single clock domain module. The same clock is used for the interconnect system interface, the SDRC interface, and all internal operations.

SMS\_CLK comes internally from the PRCM module and runs at the L3 interconnect frequency. It is also used as a functional clock for the SMS module.

The source of the SMS\_CLK is the PRCM CORE\_L3\_ICLK output: CORE\_L3\_ICLK belongs to the L3 interconnect clock domain.

### 11.2.3.1.1.2 SDRC

The SDRC is a single-clock domain module. The same clock is used for the interconnect and the memory interface. The SDRC\_CLK clock comes from the PRCM and runs at the L3 interconnect frequency. SDRC\_CLK is also used as a functional clock for the SDRC.

The SDRC\_CLK clock source is the PRCM CORE\_L3\_ICLK output: CORE\_L3\_ICLK belongs to the L3 interconnect clock domain.

An SDRC\_CLKX2 clock is provided by the PRCM at a double frequency of the SDRC\_CLK clock. This clock can be used in the LPDDR write path, depending on the configuration.

As a power-saving feature, when the SDRC no longer requires the clock domain, the software can disable it at the PRCM level by setting the EN\_SDRC bit in the PRCM.CM\_ICKLEN1\_CORE[1] register.

---

**NOTE:** The domain clock is shut down only if all other modules that receive the clock are capable and ready to accept this idle request and have IdleAck asserted.

---

For details, see [Chapter 4, Power, Reset, and Clock Management](#).

### 11.2.3.1.2 Hardware Reset

Global reset of the SDRC is done by activating the CORE\_RST signal in the CORE\_RST domain (see [Chapter 4, Power, Reset, and Clock Management](#)).

There is one global reset signal, SDRC\_GLOBALRESET, which is qualified by the signal SDRC\_POWERON. This qualification differentiates whether the signal is a cold reset or a warm reset.

- On a cold reset (that is, the power-on reset, when SDRC\_POWERON = 0 and SDRC\_GLOBALRESET is applied), all registers and state-machines within the SDRC are asynchronously reset.
- On a warm reset (that is, any other system reset condition under control of the chip top-level power manager, SDRC\_POWERON = 1 when SDRC\_GLOBALRESET is applied), the SDRC registers and the FSM are not reset, but the external SDRAM memory can be optionally placed in self-refresh mode, depending on the configuration of the SDRC.SDRC\_POWER\_REG[7] SRFRONRESET bit.

### 11.2.3.1.3 Software Reset

The SMS and SDRC modules can be reset under software control through the SMS.SMS\_SYSCONFIG[1] SOFTRESET and SDRC.SDRC\_SYSCONFIG[1] SOFTRESET bits, respectively.

A software reset has the same action as a hardware cold reset; that is, the FSM and all registers are reset immediately and unconditionally.

### 11.2.3.1.4 Power Management

The SDRC power is supplied by the CORE power domain. For details, see [Chapter 4, Power, Reset, and Clock Management](#).

The dynamic voltage and frequency scaling (DVFS) technic is described in the following section while other power-saving features and different idle modes are described in [Section 11.2.4.4, SDRC](#).

#### 11.2.3.1.4.1 Dynamic Voltage and Frequency Scaling

If the input clock SDRC\_CLK from the PRCM module is changed during operations, the DLL may enter an undefined state and memory accesses may be corrupted. For this reason, it is necessary to manually assert the SDRC\_IDLEREQ signal before any clock frequency change. This manual access is done through a register in the chip clock controller. The SDRC then finishes processing all open transactions. If this option is activated in the SDRC\_POWER\_REG[6] SRFRONIDLEREQ bit, it puts the memory into self-refresh. When done, it unlocks the DLL and puts it into a power-down state, through the SDRC.SDRC\_DLLA\_CTRL[6:5] DLLMODEONIDLEREQ field. The SDRC then asserts the

SDRC\_SIDLEACK signal and the input clock frequency can be changed or stopped, depending on the scenario. After the input clock is stable again, SDRC\_IDLEREQ is de-asserted. The DLL then relocks and the SDRC can be accessed normally. Putting the DLL in idle mode during the clock frequency change is required because it cannot automatically relock. It might get into a non-functional state and a new manual DLL configuration phase would then be required, with the risk of corrupting accesses in the mean time.

### **11.2.4 SDR Subsystem Functional Description**

The SMS optimizes the SDRAM memory usage to provide:

- The QoS level required by each of the initiators in the system
- A VRFB module (also called the 2D rotation engine) that minimizes the SDRAM page-miss penalty when accessing rotated (that is, nonsequentially addressed) lines in a graphic frame buffer

#### **11.2.4.1 SDRAM Memory Scheduler**

The SMS module is split into the following subsystems:

- L3 interconnect slave port
- VRFB: Rotation engine (RE)
- Configuration register file
- Request buffers
- Arbitration logic
- SDRC interface: master port
- Debug port
- Response buffer

[Figure 11-48](#) shows the top-level diagram of the SMS.

Figure 11-48. SMS Top-Level Diagram

sdr-008

### 11.2.4.1.1 Memory Access Scheduling

**NOTE:** For a description of the SMS mode of operation and arbitration policy, see [Section 11.2.6, SDRC Use Cases and Tips](#).

The SMS includes a set of FIFOs to queue the requests received from the system interconnect or processed by the RE. The FIFO entry contains a complete interconnect request, plus internal qualifiers added by the RE which are required to correctly process the requests modified (or generated) by the RE.

The SMS also includes a response FIFO, which is shared by all response threads. This FIFO provides full support for the response flow-control interconnect extension (handshake protocol).

When a memory transaction request arrives in the memory-access scheduler after being processed by the VRFB module, the request is sent to one of eight FIFO queues.

The allocation to a particular queue is fixed and depends on the source of the request. To prioritize concurrent transactions and optimize memory usage, each FIFO queue (and hence the memory-access request source) is categorized into one of these three arbitration classes:

- **Class 0 (highest priority):** For bandwidth-sensitive devices with severe real-time constraints. The system fails when the bandwidth requirement is not met. LCD or video display cores, camera capture cores belong to this category.
- **Class 1:** For latency-sensitive devices where system performance degrades severely when the average memory-access latency increases. These initiators also generally have some significant bandwidth requirements. All CPU cores are class 1 initiators.
- **Class 2:** For all other devices, possibly with high-bandwidth requirements but without being too latency-sensitive. Associated initiators may also have significant requirements in terms of bandwidth, but if the bandwidth budget requirement cannot be serviced, the system performance degrades, but remains functional (the system does not fail). General-purpose system DMA, multimedia accelerators (graphics, imaging, video) belong to this category.

The arbitration between Class 1 and Class 2 is programmable.

[Table 11-98](#) shows the mapping of FIFO queues and memory-access request sources to arbitration classes.

**Table 11-98. Arbitration Class Allocation**

Class	FIFO Queue	Source Device
0	6	D2D
	7	Display and Camera subsystems
1	0	MPU subsystem (instruction and data access)
	1	IVA2 subsystem (instruction, data access, and MMU)
2	2	IVA2 subsystem DMA (read and write), sDMA WR
	3	SGX
	4	USB (HS + FS), DAP
	5	sDMA (read)

A 2-level arbitration scheme determines the FIFO queue from which the next memory transaction is granted.

**NOTE:** In the register description, a group represents a FIFO queue of requests from the initiator.

### 11.2.4.1.2 Arbitration Policy

A 2-level arbitration scheme is implemented to grant access to the SDRC. The arbitration uses fully combinatorial logic, and the granted request is clocked before being issued on the interface master port of the SDRC.

- **Intra-class arbitration:** A first level of arbitration is done in parallel within each class between the

different thread groups (request FIFOs).

- Interclass arbitration: A second level of arbitration is done among the three winners of the in-class arbitration.

#### 11.2.4.1.2.1 Arbitration Policy Within a Burst and at a Burst Boundary

Arbitration is performed on the transaction boundary. The transaction can be either a single transaction or a burst transaction.

- Within a burst, if the thread cannot provide the subsequent request of the burst, a mechanism provides a wait for one idle cycle before moving the arbitration grant to the next thread. If only one idle cycle appears on one thread, an arbitration grant must not move (the next request served must be from the same thread). One idle cycle is then inserted in the SDRC request path.
- If the thread still cannot provide the request in the next cycle, the slot can be awarded to another initiator to avoid locking the SDRAM resource, if a thread cannot supply a subsequent request within the burst. In this case, there must not be a second idle cycle insertion in the SDRC request path. A burst with fewer than two idle cycles cannot be interrupted by a higher priority request.
- On burst boundary, the arbitration does not wait one idle cycle before moving the arbitration grant. As soon as the thread cannot request one transaction at a burst boundary, the arbitration grant can move to the next thread.

This is also valid within the ExtendedGrant and NOfServices windows; as soon as the thread cannot request a transaction, the arbitration grant can move to the next thread. For more information, see the following descriptions of the ExtendedGrant and NOfServices features.

#### 11.2.4.1.2.2 Burst-Complete Feature (*BURST-COMPLETE* Field in *SMS\_CLASS\_ARBITER0*, *SMS\_CLASS\_ARBITER1*, and *SMS\_CLASS\_ARBITER2*)

A burst request can be submitted to the arbitration either as soon as the first request of the burst is received by the SMS or when at least one complete burst is buffered into the FIFO. The behavior is programmable on a per-group basis using the *BURST-COMPLETE* field of the [SMS\\_CLASS\\_ARBITER0](#), [SMS\\_CLASS\\_ARBITER1](#), and [SMS\\_CLASS\\_ARBITER2](#) registers. A per-FIFO counter tracks the number of complete bursts in a FIFO.

#### 11.2.4.1.2.3 ExtendedGrant Feature (*EXTENDEDGRANT* Field in *SMS\_CLASS\_ARBITER0*, *SMS\_CLASS\_ARBITER1*, and *SMS\_CLASS\_ARBITER2*)

*EXTENDEDGRANT* is a programmable control field that allows a group to be granted for N consecutive transactions (single or burst), assuming the group is still requesting service (FIFO is not empty). *EXTENDEDGRANT* is applicable on a single/burst boundary. This multiple-service grant is intended to take advantage of the high probability of two consecutive transactions within a group accessing consecutive memory addresses (that is, in the same SDRAM page). This mechanism does not apply to consecutive transactions that have been split by the RE. The maximum number of consecutive grants is given in the *EXTENDEDGRANT* field of the [SMS\\_CLASS\\_ARBITER0](#), [SMS\\_CLASS\\_ARBITER1](#), and [SMS\\_CLASS\\_ARBITER2](#) registers. The allowed range is 1 to 3.

The ExtendedGrant logic is in the internal class arbitration but must be propagated to the interclass arbitration. The flag qualifying a second-service request is provided to the interclass arbiter so the extended grant scheme can be applied at the second level of arbitration.

- Class 0 requests can still override the ExtendedGrant scheme of class 1/class 2. Within an ExtendedGrant window, hand-over to another class/thread (granting another thread) can occur as soon as one idle cycle appears in the thread at burst or single boundary.
- The PWM counter of the interclass arbitration obeys the ExtendedGrant completion before handing priority to the other class.
- When a split transaction from the RE is interleaved within an ExtendedGrant window, completion of the ExtendedGrant window starts with the last ExtendedGrant counter value (not the initial value), because there are two independent counters for ExtendedGrant and NOfServices. The ExtendedGrant counter is reloaded to its programmed value when it reaches 0.

#### 11.2.4.1.2.4 NOFServices Feature (SMS.SMS\_CLASS\_ROTATIONm[4:0] NOFSERVICES Field)

NOFSERVICES is a programmable control field that allows consecutive transactions (single or burst) coming from the VRFB (with an RE\_split qualifier) to be granted consecutively, assuming the group is still requesting service (FIFO is not empty). NOFServices is applicable to the RE single/burst boundary. The maximum number of consecutive grants is given by the NOFSERVICES field of the SMS.SMS\_CLASS\_ROTATIONm registers. The allowable range is 1 to 31.

The NOFServices logic is in the internal class arbitration, but must be propagated to the interclass arbitration. The flag qualifying a second-service request is provided to the interclass arbiter so the extended grant scheme can be applied at the second level of arbitration.

- Class 0 requests can still override the NOFServices scheme of class 1/class 2. Within a NOFService window, hand-over to another class/thread (granting another thread) can occur as soon as one idle cycle appears in the thread at burst or single boundary. A burst with fewer than two idle cycles cannot be interrupted by a class 0 request.
- The PWM counter of the interclass arbitration obeys the NOFServices completion before handing priority to the other class.
- When a split transaction from the RE is interleaved within an ExtendedGrant window, completion of the NOFservices window starts with the last NOFServices counter value (not the initial value), because there are two independent counters for ExtendedGrant and NOFServices.

If a transaction split by the VRFB follows a nonsplit transaction currently being executed on the SDRC side, an arbitration slot occurs on the nonsplit transaction boundary, regardless of the status of the ExtendedGrant counter. This is because the chances of a nonsplit transaction and a split transaction accessing the same SDRAM page are low. Similar behavior would be observed for a split transaction followed by a nonsplit transaction. The NOFServices counter is reloaded with its programmed value when it reaches 0.

#### 11.2.4.1.3 Internal Class Arbitration

Class 0, class 1, and class 2 internal arbitrations are performed according to the following rules:

- Within a class, a standard least-recently-used (LRU) policy is applied. The LRU thread, if not empty, is granted when an arbitration decision occurs. LRU is applied taking into account the ExtendedGrant/NOFServices counter status. Grant is given to another nonempty LRU thread only if the current thread is serviced for ExtendedGrant/NOFServices times.
- On top of the LRU policy, a high-priority group can be defined through the SMS.SMS\_CLASS\_ARBITERO[7:6] HIGHPRIOVECTOR field. The high-priority group is unique and programmable. If a high-priority thread in a class, which was previously empty, starts requesting service, the current thread that has been given grant is completely serviced as per ExtendedGrant/NOFServices strategy and then the grant is given to the high-priority thread.

##### 11.2.4.1.3.1 Interclass Arbitration

The interclass arbitration is managed using a time-varying policy driven by the following rules:

- The interclass arbitration is a PWM-like (Pulse Width Modulation) logic that defines two request-based windows:
  - Class 1 has higher priority than class 2 during M requests of class 1, where M is defined by the CLASS1PRIO parameter.
  - Class 2 has higher priority than class 1 during the next N requests of class 2, where N is defined by the CLASS2PRIO parameter. For more information on priority between classes, see [Section 11.2.6.2.2.3](#).
- The PWM counter is decremented each time the class is processing a single 64-bit request in its high-priority window.
- A class 0 request always has the highest priority. The PWM counter is frozen while class 0 requests are being serviced.
- A class 1 transaction can be serviced during the class 2 high-priority window if class 2 is not requesting service (conversely, a class 2 transaction can be serviced during the class 1 high-priority window if class 1 is not requesting service). The PWM counter is frozen when the grant is given to the

thread that is not in its high-priority window.

- NOFservices/ExtendedGrant have higher priority than the PWM counter.
- The PWM counter is reloaded with M and N when it reaches 1 and an arbitration decision must be made.
- The priority order is as follows:
  - Current burst service lock (assuming subsequent burst requests available when required)
  - Class 0
  - ExtendedGrant and NOFservices atomicity (assuming subsequent burst requests available when required)
  - Class 1 if PWM priority is to class 1; class 2 if PWM priority is to class 2
  - Class 2 if PWM priority is to class 1; class 1 if PWM priority is to class 2

#### 11.2.4.1.4 Firewalls

Access permissions can be defined in the target memory address space on a per-initiator basis. Initiators are differentiated using the interconnect ConnID extension.

Permissions are allocated to the various initiators on a per-region basis. The memory regions are programmable using a start address and an end address that are defined with 64K-byte granularity. Up to seven distinct regions can be defined; the software must ensure that they do not overlap.

The remaining memory space (total memory space minus the protected areas) is defined as region 0.

Depending on whether the access is a read or a write, and depending on the in-band request qualifiers, a region may be given specific access permissions. When an access is received by the SMS, the access checked against the access attributes.

- The read permission is initiator-based and is controlled using the SMS.SMS\_RG\_RDPERMi register.
- The write permission is initiator-based and is controlled using the SMS.SMS\_RG\_WRPERMi register.
- The REQINFO bits taken into account are the incoming MReqInfo attributes: Debug, privilege, and attribute, along with the host parameter decoded in the SMS module (see the SMS.SMS\_RG\_ATTi[31:0] REQINFO field). For the SMS firewall, the host parameter is set for the MPU initiator and the sDMA initiator. The decoding of the host parameter, based on the MPU ConnID and sDMAConnID generic parameters (defined at design time), is done inside the SMS module.
- Whether the access is accepted (there is one valid bit for each ReqInfo pattern) can be specified for each ReqInfo pattern. ReqInfo permission is controlled using the region attributes register SMS.SMS\_RG\_ATTi[31:0] REQINFO field.

Table 11-99 lists the ReqInfo parameters ordering.

**Table 11-99. ReqInfo Parameters Ordering**

Host	Privilege	Reserved for Non-GP Devices	Debug	Type	Req Info	SMS.SMS_RG_ATTi[31:0] REQINFO Field
0: Nonhost 1: Host	0: User 1: Supervisor	Reserved	0: Functional 1: Debug	0: Data Transfer 1: Opcode Fetch		
		N/A <sup>(1)</sup>				0b0...000000000
0	0	0	0	0	0	0b0...000000001
0	0	0	0	0	1	0b0...000000010
0	0	0	1	0	2	0b0...000000100
					...	
0	1	1	1	0	14	0b0...000001...00
0	1	1	1	1	15	0b0...00001...000
1	0	0	0	0	16	0b0...0001...0000
1	0	0	0	1	17	0b0...001...00000
					...	
1	1	1	0	1	29	0b0010...000000

<sup>(1)</sup> Access to the region is not allowed

**Table 11-99. ReqInfo Parameters Ordering (continued)**

Host	Privilege	Reserved for Non-GP Devices	Debug	Type	Req Info	SMS.SMS_RG_ATTi[31:0] REQINFO Field
0: Nonhost 1: Host	0: User 1: Supervisor	Reserved	0: Functional 1: Debug	0: Data Transfer 1: Opcode Fetch		
1	1	1	1	0	30	0b0100...000000
1	1	1	1	1	31	0b1000...000000

When all [SMS\\_RG\\_ATTi\[31:0\]](#) REQINFO bits are set to 0 the access to the region is not allowed.

Set the REQINFO[0] bit to 1 when NonHost-User-Functional-Data accesses are permitted in this region.

Set the REQINFO[1] bit to 1 when NonHost-User-Debug-Data accesses are permitted in this region.

Set the REQINFO[31] bit to 1 when Host-Supervisor-Debug-Opcode accesses are permitted in this region.

Any bit of the [SMS\\_RG\\_ATTi\[31:0\]](#) REQINFO field corresponds to a particular combination of the five attribute bits. When all [SMS\\_RG\\_ATTi\[31:0\]](#) REQINFO bits are set to 1 the region is full-access allowed.

The firewall unit performs the following checks to authorize or reject an access to the external memory:

- Compute the Region ID based on the transaction address.
- Generate a violation if overlapping of firewall regions is detected.
- From the Region ID, get the attributes for the region that has been hit.
- Check the transaction REQINFO attributes with respect to the region attributes (debug, privilege, type, and host).
- Reject the transaction if the attributes are not compatible.
- From the Region ID and the transaction qualifiers (MCmd, ConnID), check the initiator permissions for performing the access (read, write).
- Reject the transaction if there is no permission.

The protection regions are organized in priority levels (from Level 0 to Level 2) to prevent problems with overlapping region and corner cases associated with them; the lowest level has the lowest priority (see [Figure 11-49](#)).

Figure 11-49. Region Organization

sdr-009

Region 0 (default region containing the whole memory space): Level 0

Region 1 (allows dynamic reprogramming of regions): Level 2

Regions 2-7 (protection regions): Level 1

Region 1 has the highest priority to perform dynamic masking of other already-programmed regions when they are reprogrammed.

Overlapping regions of the same priority level is forbidden and results in a violation when an access to the concerned region occurs. This violation is reported in the error-log register. Priority-level handling is done in the hardware; it does not involve any specific software development.

All transactions are checked, including those the RE has processed.

When detecting a violation on an incoming request, the SMS respects the response ordering within the faulty thread.

A violation flag is raised internally and the MThreadID field is logged. Generation of the interconnect error response is then local to the SMS; the response buffer must be used to manage the potential response collision with regular SDRC responses.

### 11.2.4.1.5 Rotation Engine

Smartphone applications must often perform image rotation between the orientation of images stored in external memory and the orientation with which they must be displayed. The device offers a hardware mechanism that allows rotation tasks to be implemented efficiently, transparent to software applications, thereby keeping the MPU and DSP CPUs free for other tasks. For a description of the RE mechanism, see [Section 11.2.6, SDR Use Cases and Tips](#).

The SMS includes address processing support for rotated LCD displays (90, 180, and 270 degrees). This function is realized by the VRFB submodule, also called the rotation engine (RE) in this document.

The primary goal of the VRFB is to eliminate the SDRAM page-miss penalty when reading graphics data in nonnatural raster scan order (that is, top to bottom, bottom to top, right to left).

The 2D-rotation module (the VRFB) is included as a black box that intercepts incoming requests when addressed to the virtual frame buffer. If the address of the request targets the VRFB address space, the request is sent to the RE. It processes the address and reinserts the modified request in the SMS request path. The SMS translates the virtual address into physical SDRAM addresses and reinserts a request or multiple requests in the SMS request path to the SDRC.

---

**NOTE:** The use of the word *virtual* does not refer to the usual CPU-related MMU concept; the word is used in a more general context of the address remapping feature, which decouples the system from the actual storage physical organization of the graphics data in the external memory.

---

The VRFB can be abstracted as a 3-port module:

- Interconnect input port
- Interconnect output port
- Configuration port; all programmable control registers are part of the SMS register file, which is described in [Section 11.2.4.1.5.3, VRFB Configuration Port](#).

#### 11.2.4.1.5.1 VRFB Input Port

The VRFB receives a 29-bit address, and two decoding signals, from the SMS module. The 29-bit address is decoded to determine the context and the rotation view of the request.

The VRFB address space is a 768-MB address space split into two non-contiguous virtual address spaces:

- Address space 0: 256 MB in quarter Q1 (start address: 0x7000 0000, end address: 0x7FFF FFFF)
- Address space 1: 512 MB in quarter Q3 (start address: 0xE000 0000, end address: 0xFFFF FFFF)

It can manage up to 12 concurrent rotation contexts. [Table 11-100](#) details the address space of each context.

**Table 11-100. VRFB Contexts Virtual Address Spaces vs Rotation Angle**

Context Number	0°	90°	180°	270°
0	0x7000 0000	0x7100 0000	0x7200 0000	0x7300 0000
1	0x7400 0000	0x7500 0000	0x7600 0000	0x7700 0000
2	0x7800 0000	0x7900 0000	0x7A00 0000	0x7B00 0000
3	0x7C00 0000	0x7D00 0000	0x7E00 0000	0x7F00 0000
4	0xE000 0000	0xE100 0000	0xE200 0000	0xE300 0000
5	0xE400 0000	0xE500 0000	0xE600 0000	0xE700 0000
6	0xE800 0000	0xE900 0000	0xEA00 0000	0xEB00 0000
7	0xEC00 0000	0xED00 0000	0xEE00 0000	0xEF00 0000
8	0xF000 0000	0xF100 0000	0xF200 0000	0xF300 0000
9	0xF400 0000	0xF500 0000	0xF600 0000	0xF700 0000
10	0xF800 0000	0xF900 0000	0xFA00 0000	0xFB00 0000

**Table 11-100. VRFB Contexts Virtual Address Spaces vs Rotation Angle (continued)**

Context Number	0°	90°	180°	270°
11	0xFC00 0000	0xFD00 0000	0xFE00 0000	0xFF00 0000

#### CAUTION

There is no protection in hardware for accesses outside the image resolution. Users can access the full virtual address range for a given context (there is no error reporting). Accessing outside of the image resolution creates aliasing within the image and is also translated as an additional physical memory space requirement on the external memory (some data outside of the image range can be overwritten by mistake). The following formula can be used to calculate the extra memory that will be accessed:  $\text{extra\_mem\_size} = (2048 - \text{image\_width\_roundedup}) \times \text{page\_height} \times \text{pixel\_size}$  with  $\text{image\_width\_roundedup} = \text{ROUNDUP}(\text{image\_width} \times \text{pixel\_size} / \text{page\_width}) \times \text{page\_width} / \text{pixel\_size}$ .

#### 11.2.4.1.5.2 VRFB Output Port

The VRFB output port can be a delayed copy of the input port, with the address field transformed. Depending on the rotated view that is active, an incoming transaction can also be split into several internal transactions.

The pipeline delay between the input and the output ports is three clock periods.

#### 11.2.4.1.5.3 VRFB Configuration Port

The configuration port allows 12 concurrent rotation settings.

The VRFB address space is a 768 MB (256 + 512) address space split into two noncontiguous spaces. It can manage up to 12 concurrent rotation settings.

The VRFB configuration port includes all the settings required to control the 12 rotation contexts. This is an input-only port. All settings are provided from the SMS control register file.

For each of the 12 contexts, the buffer physical base address, image height and width, and pixel size can be configured through the following registers (where n is the context number, from 0 to 11):

- SMS.SMS\_ROT\_PHYSICAL\_BAn[30:0] PHYSICALBA field
- SMS.SMS\_ROT\_SIZE n[26:16] IMAGEHEIGHT and SMS.SMS\_ROT\_SIZE n[10:0] IMAGEWIDTH fields
- SMS.SMS\_ROT\_CONTROL n[1:0] PS field

The memory arrangement for the pixels of a frame buffer accessed through the RE is tile-based. A tile is a rectangular array of pixels. The tile size should match the page size of the SDRAM component attached to the controller for optimal performance.

The tile size is defined using the SMS.SMS\_ROT\_CONTROL n[10:8] page height (PH) and [6:4] page width (PW) fields.

The image height and image width (SMS.SMS\_ROT\_SIZE n[26:16] IMAGEHEIGHT and [10:0] IMAGEWIDTH fields, expressed in bytes) must be multiples of the tile height and width, respectively. Some padding is required if the image size does not fit this requirement.

For a configuration example, see [Section 11.2.5.1.2, VRFB Context Configuration](#).

#### 11.2.4.1.6 Violation Reporting

The SMS firewall can detect violations and report them to the overall system by using the following qualifiers:

- The in-band error response to a non-authorized access

- The out-of-band error signal generation using two out-of-band error signals

Based on the fact that there is no way to prevent the debugger from generating firewall violations during debug, and that users cannot stop checking for functional violations, two out-of-band violation signals are set when:

- A functional violation is detected
- A debug violation is detected

These signals are asserted on each error detection from a read, write, or posted write faulty access: they are deasserted when the software clears the error bit in the [SMS\\_ERR\\_TYPE](#) register.

#### 11.2.4.2 Module Power Saving

Power-saving is managed through the SMS.[SMS\\_SYSCONFIG](#) register.

The [SMS\\_SYSCONFIG\[4:3\]](#) SIDLEMODE field defines the power management strategy (force idle mode, no idle mode, or smart idle mode). See [Section 11.2.4.3](#) for more details about the system power management.

By default, the internal interface clock gating strategy is enabled as the [SMS\\_SYSCONFIG\[0\]](#) AUTOIDLE bit is set to 0x1 after reset. When all FIFO queues are empty and no ongoing transactions remain, the L3 interconnect clock is disabled inside the SMS thus reducing power consumption. The L3 interconnect clock can be disabled after a programmable delay defined in the [SMS\\_POW\\_CTRL\[7:0\]](#) IDLEDELAY bit field.

When there is new activity on the interconnect interface, the interconnect clock is restarted without any latency penalty. It is recommended to enable this mode to reduce power consumption.

There is an internal interface clock gating strategy within the SDRC. This power-saving feature is always active.

#### 11.2.4.3 System Power Management

The SMS can be configured through the SMS.[SMS\\_SYSCONFIG](#) register to be in one of these idle modes:

- No-idle mode (the SMS.[SMS\\_SYSCONFIG\[4:3\]](#) SIDLEMODE field is set to 0x1): The module never goes into idle state.
- Force-idle mode (the SMS.[SMS\\_SYSCONFIG\[4:3\]](#) SIDLEMODE field is set to 0x0): The module goes into idle state immediately after receiving the request from the PRCM.
- Smart-idle mode (the SMS.[SMS\\_SYSCONFIG\[4:3\]](#) SIDLEMODE field is set to 0x2): SidleAck is asserted once the module has confirmed there are no more outstanding transactions with the SDRC.

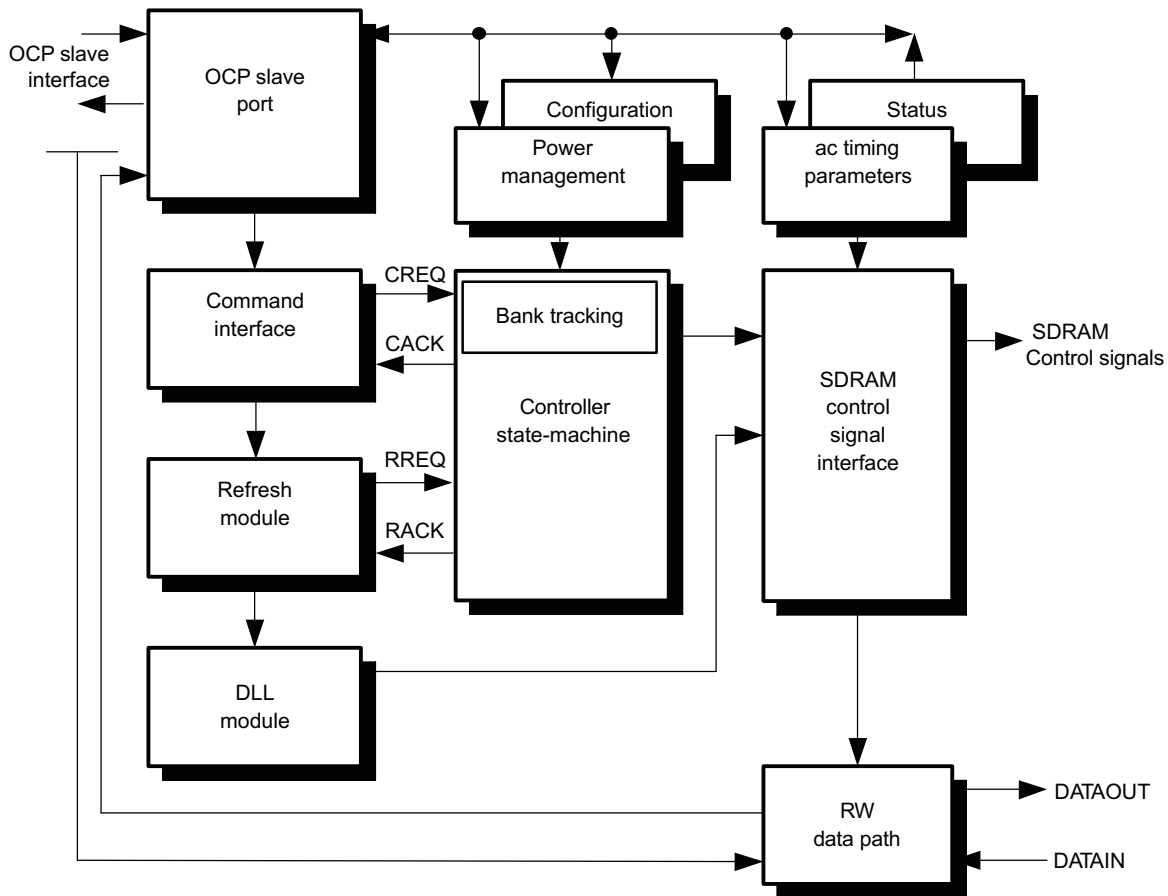

#### 11.2.4.4 SDRC

The SDRC provides two configurable memory areas. Each supports mobile SDR SDRAM and low-power DDR SDRAM from 16 Mbitsto 4 Gbits, depending on the memory organization.

Flexible row/column addressing schemes are possible with 2-bank support for 16 Mbits and 32 Mbits memories, and 4-bank support for 64 Mbits, 128 Mbits, 256 Mbits, 512 Mbits, 1 Gbit, 2 Gbits, and 4 Gbits memories.

[Figure 11-50](#) shows the architecture of the SDRC.

Figure 11-50. SDRC Architecture

sdrc-010

#### 11.2.4.4.1 CS0-CS1 Memory Spaces

##### 11.2.4.4.1.1 Chip-Select 0 Start Address

- CS0 always starts at address 0 with respect to the local interconnect address.
- The valid CS0 range is 0–CS0max, where CS0max is defined in the SDR.C.SDR.C\_MCFG\_p[17:8] RAMSIZE field where p = 0 (for CS0), and by the number of banks.

##### 11.2.4.4.1.2 Chip-Select 1 Start Address

- CS1 start address is programmable.
- The default base address for CS1 after reset is defined in the register description.
- The SDRC 1G-byte/8G-bit address space is segmented so that 7 possible CS1 start address locations (8 in total minus 1 reserved for CS0) are defined by the SDR.C.SDR.C\_CS\_CFG[3:0] CS1STARHIGH field as shown in Figure 11-51.
- Each 128M-byte address space is also segmented into 32M-byte address spaces defined by the SDR.C.SDR.C\_CS\_CFG[9:8] CS1STARTLOW field so that 64 possible CS1 start address locations are defined by the SDR.C.SDR.C\_CS\_CFG[3:0] CS1STARHIGH and SDR.C.SDR.C\_CS\_CFG[9:8] CS1STARTLOW fields.
- The valid CS1 range is:  
CS1 start address slot–CS1max, where CS1max is defined by SDR.C.SDR.C\_MCFG\_p[17:8] RAMSIZE where p = 1 (for CS1) and SDR.C.SDR.C\_CS\_CFG registers.

**Figure 11-51. CS0/CS1 Chip-Select Start Address Slots**

sdr0-011

#### 11.2.4.4.1.3 SDRAM Memory Combinations on CS1 and CS0

The combinations of SDR and DDR memories/SDRAMs are defined as follows:

- SDR and DDR memories can be connected on either CS1 or CS0.
- The only restriction on the coexistence of SDRAMs on CS0 or CS1 is that a combination of SDR on one CS and DDR on the other CS is not allowed.

The SDRAM data bus width on each CS is determined by the SDRC.SDRC\_SHARING[11:9] CS0MUXCFG and SDRC.SDRC\_SHARING[14:12] CS1MUXCFG fields of the memory-sharing registers.

#### 11.2.4.4.2 Bank Tracking

The main state-machine controls all the accesses to external memories.

The SDRC contains hardware for tracking open pages on a per-bank basis. Up to four open pages are tracked per CS, for a maximum of eight open pages tracked.

To pipeline accesses efficiently, the SDRC includes a request look-ahead FIFO that analyzes interconnect requests with respect to the status of the target banks. A bank status can be any of the following:

- Bank open on another row
- Bank closed
- Bank open on the same row

The SDRC state-machine generates the appropriate sequence of memory commands. All precharge and active commands are hidden as much as possible, to optimize the memory bandwidth usage.

The look-ahead FIFO depth is 9 x64-bit requests, with a limit of four different transactions. As soon as the look-ahead FIFO stores four complete transactions or when it is full, the SCmdAccept is deasserted and any incoming request is blocked.

Requests sent to the SDRC are treated in order. The four transactions limit in the SDRC look-ahead FIFO ensures that high-priority requests performance is not hampered by a succession of SDRAM page close/page open cycles due to previous lower priority requests already accepted by the SDRC. With this limit, requests not accepted by the SDRC will have to go through the SMS arbitration at a later time. If a high-priority request has arrived in the SMS in the mean time, it will be passed to the SDRC before any lower-priority request, as defined in the regular SMS arbitration scheme.

#### 11.2.4.4.3 Address Multiplexing

A flexible address scheme allows for the support of any new type of SDRAM address multiplexing and density.

The programming model has changed but is still compatible with the legacy fixed address scheme. Both chips, hence both CS must use the same address scheme (fixed or flexible), but can use different address multiplexing configurations.

A dedicated bit controls the address scheme used: the legacy fixed address scheme or the new flexible address scheme:

- The legacy fixed address scheme is selected when the SDRC.SDRC\_MCFG\_p[19] ADDRMUXLEGACY bit is set to 0 (where p = 0 or 1 for SDRC CS0 or CS1).
- A new flexible address-muxing scheme configuration is selected with the SDRC.SDRC\_MCFG\_p[19] ADDRMUXLEGACY bit set to 1 (where p = 0 or 1 for SDRC CS0 or CS1).

To use this new flexible address scheme, configure the row address width and the column address with the SDRC.SDRC\_MCFG\_p[26:24] RASWIDTH and SDRC.SDRC\_MCFG\_p[22:20] CASWIDTH fields.

For more information about fixed address multiplexing configurations for SDRAM components, see [Section 11.2.2.2.3, Address Multiplexing](#).

#### 11.2.4.4.4 Bank Allocation Setting

##### 11.2.4.4.4.1 System Address Decoding

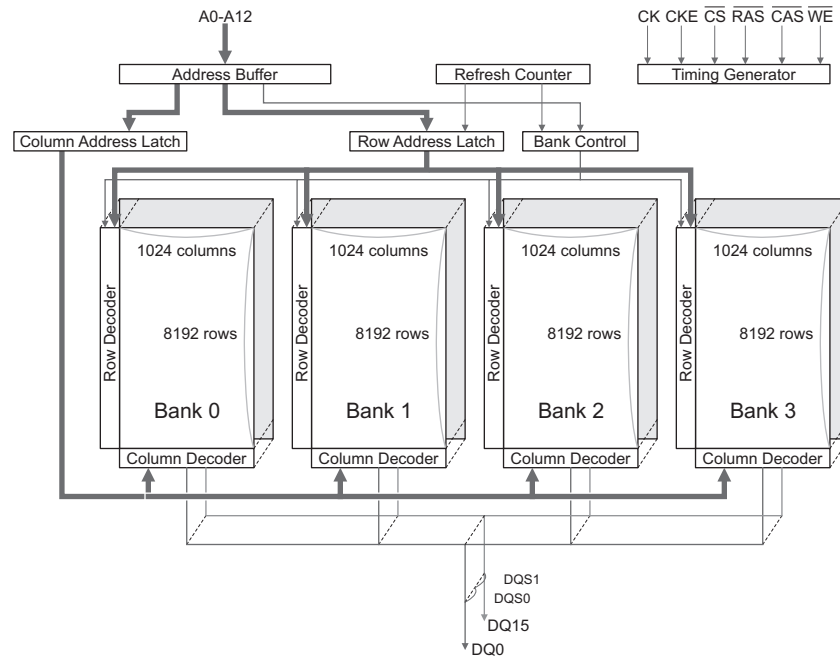

The SDRC has a 64-bit slave interface connected to the L3 main system interconnect. The regular allocation is to see the system address bus as the concatenation bank-row-column. The SDRC translates the interconnect request (read or write to memory for instance) into a series of commands and bank, row, column signals. The commands are sent to the external SDRAM through the `sdrc_ncs`, `sdrc_nras`, `sdrc_ncas` and `sdrc_nwe` signals. The bank, row and column addresses are sent through `sdrc_a` and `sdrc_ba` with the associated command. Those words can be defined as follow:

- Bank: the address of one of the four (or two) banks
- Row: the address of a page
- Column: the address of a word in a page

The bank signals are used to select which of the bank is accessed when transferring data from or to the SDRAM. In the first cycle, the SDRAM memory latches the row address (`nRAS` low): the adequate bank and row are activated. Next cycle, the SDRAM memory latches the column address (`nCAS` low): the adequate column is activated. The address is hence decoded: memory cells are sensed by sense amplifier and data is read from or written to output buffers.

[Figure 11-52](#) shows a block diagram of a 512 Mbits SDRAM memory (8M x 16 x 4 banks). The data bus `DQ[15:0]` has a 16-bit width. Rows are addressed through `A0-A12` (8192 rows) and columns through `A0-A9` (1024 columns).

**Figure 11-52. SDRAM Controller Block Diagram**

sdr-042

#### 11.2.4.4.2 SDRC Commands

Before any read or write command can be issued to a bank in the external memory, a row in that bank must be opened. This is accomplished by the active command, by which the bank and the row are selected. More than one bank (up to four according to the memory used) can be active at one time. Once a row is opened, a read or write command can be issued to that row. The row remains active until a precharge or read/write to another row in the same bank or a refresh to the bank occurs.

Autorefresh command is used during normal operation mode. This command is non-persistent (that is, it must be issued each time a refresh is required). The device requires a refresh of all rows in a periodic interval. This command takes some time (according to the memory used), and during this phase no read or write command can be processed. A precharge-all (that is, a precharge command affecting all banks) is issued before any autorefresh sequence.

An active command to a row of a bank for which another row is already active can be issued only after the previous row has been closed. The precharge command is used to deactivate the open row in a particular bank. The bank is available for a subsequent row access some time after the row precharge command is issued. A minimum time is needed to close and open a new row.

A subsequent active command to another bank can be issued while the first bank is being accessed without closing the row in the first bank. This results in a reduction of row access time in the same bank. In this case, it is not necessary to deactivate (with a precharge command) the row in the other banks. Up to four banks, depending on the memory used, can be activated at the same time. In each bank, one row can be selected at a time.

#### 11.2.4.4.3 BANKALLOCATION Parameter

To optimize SDRAM memory accesses in a throughput point of view, the SDRC supports various bank-row-column allocation. The bank-row-column allocation choice depends on many parameters, such as the number of initiators in the use case, the memory usage (accesses bandwidth, frequency), and so on.

The SDRC not only supports the regular allocation where the system address bus is seen as the concatenation bank-row-column, but it also supports two other types of allocation. The [SDRC\\_MCFG\\_p\[7:6\]](#) BANKALLOCATION bit field (where p = 0 or 1 for CS0 or CS1) selects the type of allocation. This feature modifies the bank, row, and column address decoding order:

- BANKALLOCATION = 0x0: Bank-row-column
- BANKALLOCATION = 0x1: Bank1-row-bank0-column
- BANKALLOCATION = 0x2: Row-bank-column

Only the flexible address-muxing scheme allows choosing different bank mapping allocations throughout the BANKALLOCATION parameter (that is, the legacy address-muxing scheme does not).

The flexible address-muxing scheme (SDRC\_MCFG\_p[19] ADDRMUXLEGACY = 0x1) allows choosing different bank mapping allocations. The SDRC.SDRC\_MCFG\_p[7:6] BANKALLOCATION bit field (p = 0 or 1 for CS0 or CS1) defines the ordering of the bank, and the column and row decoding of the incoming system address. The BANKALLOCATION bit field can be set on a CS basis.

In the usual allocation, the system address bus is seen as a concatenation of bank-row-column. For instance, consider the SDRAM used in Section 11.2.6.3, *Typical SDRC Connection to an External SDRAM Device*: a 512-Mbit SDRAM (8M x 16 x 4 banks). The system address received from the interconnect into the SDRC is composed of:

- 2 system address bits used as the bank address (going to SDRC sdr\_c\_ba[1:0] pins)
- 13 system address bits used as the row address (going to SDRC sdr\_c\_a[12:0] pins)
- 10 system address bits used as the column address (going to SDRC sdr\_c\_a[12:0] pins)

Setting the BANKALLOCATION bit field to 0x1 or 0x2 changes the order of the system address decoding, as shown in Figure 11-53.

**Figure 11-53. Address Multiplexing Scheme According to BANKALLOCATION**

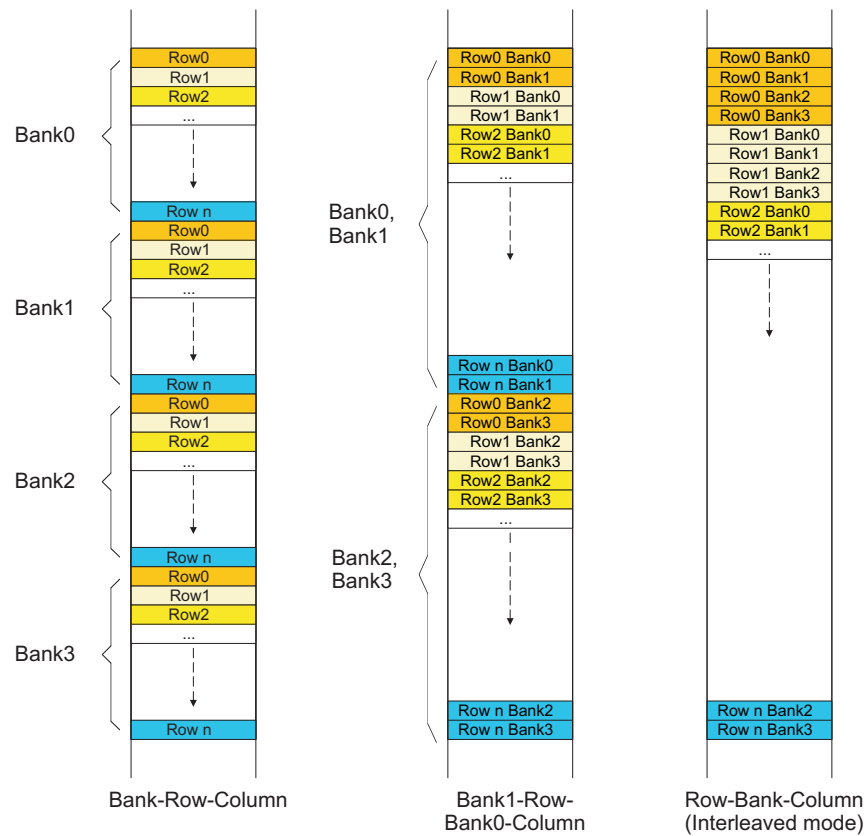

Figure 11-54 compares bank-row-column and row-bank-column memory accesses.

**Figure 11-54. Simplified View of Bank-Row-Column vs Row-Bank-Column Bank Allocation**

sdr\_044

The latency to charge another row in the same bank (that is, to close the opened page and to open another one) is bigger than the latency involved with an access to a given row in another bank. By moving bank select signals ahead of column and after row addresses, bank interleaving is likely to happen more often. More frequent use of the interleaved mode means less overall SDRAM access time and, thus, yields to better overall performance.

In some use cases, several initiators access the same bank (bank0 for instance) in external SDRAM memory at the same time. With this kind of scenario, a lot of penalties are added because of rows opening and closing. The BANKALLOCATION setting improves the latency for reading and writing operations by optimizing memory accesses through the reduction of deactivate sequence use, thereby reducing time penalties.

The bank1-row-bank0-column allocation is a good compromise between the legacy bank allocation (bank-row-column) and the full interleaving bank allocation (row-bank-column). In some use cases, it may be necessary to keep only half of the memory refreshed (on bank0 and bank1 for instance) while the other two banks are unused. In full interleaving bank allocation, the memory must be refreshed through the self-refresh mode, while with bank1-row-bank0-column, the memory can be refreshed through self-refresh mode or through partial array self-refresh mode.

In the following, an example of latency is given based on a 512-Mbit SDRAM memory data sheet. [Table 11-101](#) gives the duration for some AC timing parameters. The frequency used in the example is 133 MHz ( that is,  $t_{CK} = 7.5$  ns). The CAS latency = 3.

**Table 11-101. Mobile DDR SDRAM AC Timing Parameters**

AC Timing Parameter	Description	Duration (ns)
tRFC	Autorefresh cycle time	80 (min)
tRP	Row precharge time	22.5 (or 3 tCK)

**Table 11-101. Mobile DDR SDRAM AC Timing Parameters (continued)**

AC Timing Parameter	Description	Duration (ns)
tRC	Row cycle time	67.5 (or 9 tCK)
tRAS	Row active time	45 (or 6 tCK)
tRCD	nRAS to nCAS delay time	22.5 (or 3 tCK)
tRRD	Row active to row active delay time	15 (or 2 tCK)

The latency to access another row in the same bank depends on tRP and tRAS timings because a precharge command followed by an active command must be issued. Therefore, 6 tCK are needed to close the current row and open another one.

When accessing another bank, the latency to access another row depends on tRAS timing only because the closing of the current row is not mandatory. In other words only an active command must be issued. Therefore, 3 tCK are needed to open another row in a different bank.

Single initiator use case:

When the initiator wants to access a page in a bank for the first time, it opens only this page. It takes 3 tCK. When the initiator is done with this page, it closes this page and opens another one. It takes 6 tCK.

Two initiators use case:

When one initiator wants to access a page in the same bank, it must necessarily close the current page and open the page it wants to access. It takes 6 tCK.

When one initiator wants to access a page this time in another bank, there can be less page opening and closing. For instance, if the initiator wants to open a page in another bank where no page is open, it takes only 3 tCK, rather than 6 tCK if it was another page in the same bank.

#### 11.2.4.4.5 Data Multiplexing During Write Operations

##### 11.2.4.4.5.1 External Bus Combinations

The SDRC pin allocation scenarios are provided in [Table 11-102](#). These scenarios are defined on a per-CS basis for maximum flexibility. The pin allocation configurations allow implementation of combinations of the 16-/32-bit external interfaces listed in this table. The data multiplexer receives a 64-bit word from the SDRAM command queue and partitions the data into a series of 16-bit or 32-bit accesses. The data multiplexer also steers the data to the appropriate data lane. The data partitioning and data steering are determined by the SDRC.[SDRC\\_SHARING](#)[11:9] CS0MUXCFG and SDRC.[SDRC\\_SHARING](#)[14:12] CS1MUXCFG fields.

**Table 11-102. SDRC Data Lane Configurations**

Device pins	sdrc_d[31:24]	sdrc_d[23:16]	sdrc_d[15:8]	sdrc_d[7:0]	
	DataLane[31:16]		DataLane[15:0]		
	DQS3	DQS2	DQS1	DQS0	
	DQM3	DQM2	DQM1	DQM0	
	D[31:0]				0x0, 0x1
	D[15:0]				0x2, 0x7
			D[15:0]		0x3
					0x4, 0x5, 0x6: Reserved

SDRC.SDRC\_SHARING[14:9]  
CSnMUXCFG field

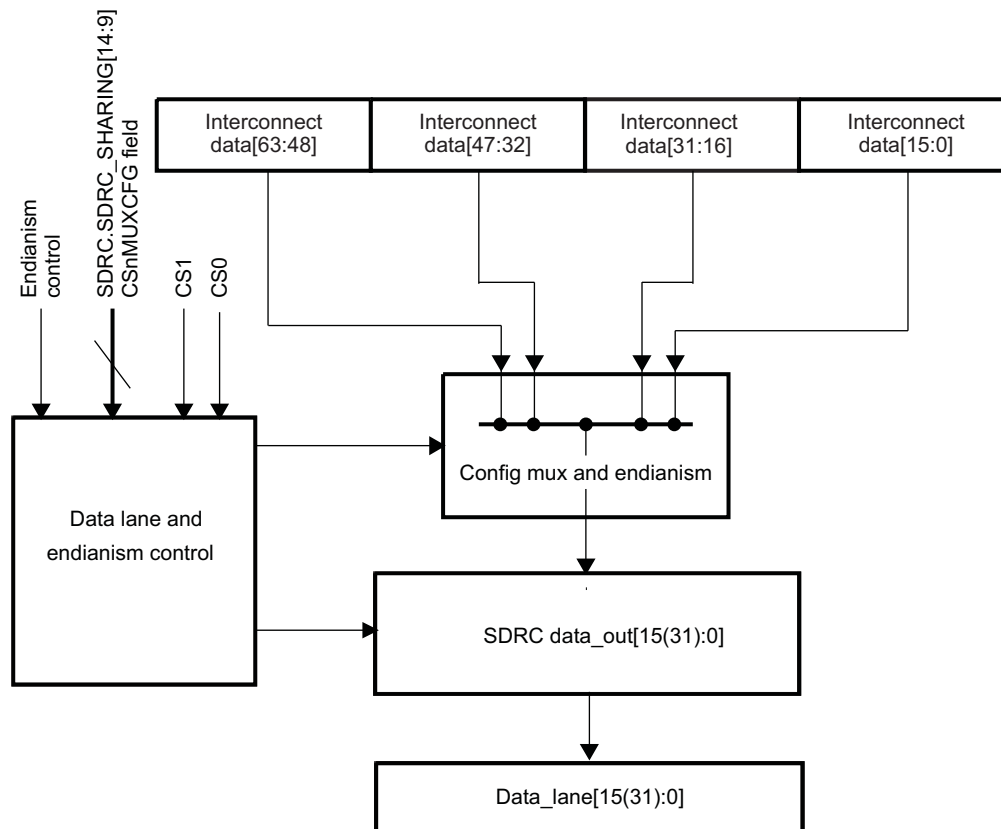

#### 11.2.4.4.5.2 Endianness-Aware Unpacking

Data transactions can be either big or little endian; the transaction endianness is determined by an in-band interconnect qualifier. Muxing 64-bit data to 16-/32-bit data is performed according to this qualifier.

For a 64-bit interconnect little-endian write transaction on a 16-/32-bit memory, Data[15(31):0] is written at the lowest memory address, and Data[63:48(32)] is written at the highest memory address.

For a 64-bit interconnect big-endian write transaction on a 16-/32-bit memory, Data[15(31):0] is written at the highest memory address, and Data[63:48(32)] is written at the lowest memory address.

Figure 11-55 shows the data multiplexing scheme.

**Figure 11-55. Data Multiplexing Scheme**

sdr-012

### 11.2.4.4.6 Data Demultiplexing During Read Operations

#### 11.2.4.4.6.1 External Bus Combinations

The SDRC pin allocation scenarios are shown in [Table 11-102](#). These scenarios are defined on a per-CS basis for maximum flexibility. The pin allocation configurations allow implementation of combinations of 16-/32-bit external interfaces. The data demultiplexer receives 16-/32-bit data from the relevant SDRC data lane, and then performs a data packing function. The packing function formats the data into 64-, 32-, 16-, or 8-bit format. The data demultiplexer also steers the data from the appropriate data lane. The data partitioning and data steering are determined by the SDRC.SDRC\_SHARING[11:9] CSOMUXCFG and SDRC.SDRC\_SHARING[14:12] CS1MUXCFG bit fields.

Figure 11-56 shows the data demultiplexing scheme.

Figure 11-56. Data Demultiplexing Scheme

sdrc-013

#### 11.2.4.4.6.2 Endianness-Aware Packing

Data transactions can be big or little endian; their endianness is determined by an in-band interconnect qualifier. Demuxing 16-/32-bit memory data to 64-bit interconnect data is performed according to this qualifier.

For a 64-bit interconnect little-endian read transaction on a 16-/32-bit memory, Data[15(31):0] is read from the lowest memory address, and Data[63:48(32)] is read from the highest memory address.

For a 64-bit interconnect big-endian read transaction on a 16-/32-bit memory, Data[15(31):0] is read from the highest memory address, and Data[63:48(32)] is read from the lowest memory address.

To preserve data integrity in all situations, that is, regardless of the effective scalar size of the transferred data (byte, Word16, Word32, or DWord64), the endianness specified during the read operation must match that specified during the write operation. If there is no match, the packing and unpacking operations are not consistent. There is no attempt to perform endianness conversion in the SDRC; only endian-aware width conversion is performed.

#### 11.2.4.4.7 Refresh Management

Refresh management can be divided as follows:

- Self-refresh management
- Autorefresh management (programmable refresh period)

##### 11.2.4.4.7.1 Self-Refresh Management

Self-refresh is entered to place an attached SDRAM into an autonomous refresh mode, typically when the OMAP device enters an idle mode and switches off the SDRAM clock.

In self-refresh, the SDRAM supplies the row address generation required to refresh and retain data in the absence of external clocking.

Self-refresh can be entered using any of the following methods:

- Manually, under software control per CS
- Upon a reset event: Automatically on a warm reset event (if the SDRC is programmed to enter self-refresh on warm reset)
- Upon a hardware request: Automatically on an idle request sent by the system power manager (if the SDRC is programmed to enter self-refresh on idle request)
- Automatically after a (programmable) period of inactivity on the interconnect interface (if enabled by setting the SDRC.SDRC\_POWER\_REG[5:4] CLKCTRL bit field to 0x2)

Self-refresh can be exited as follows:

- Manual software command (exit from self-refresh mode; see [Section 11.2.5.3.4, DLL/CDL Configuration](#))
- Automatically after receiving a read or write transaction to access memory

##### 11.2.4.4.7.2 Autorefresh Management

When autorefresh is enabled, a programmable hardware counter within the SDRC generates a periodic event that triggers either a single refresh or a burst of consecutive refresh commands. This is the standard refresh mode used when the system is active, while the running applications regularly access the SDRAM.

An autorefresh command can also be applied using the SDRC.SDRC\_MANUAL\_p register (see [Section 11.2.5.3.4, DLL/CDL Configuration](#)). This method can be used to generate a device-specific initialization sequence after power up or after the memory device exits from a low-power mode (self-refresh or deep-power-down).

The autorefresh request period is a user-controlled parameter programmed to meet the specification of the memory devices. Each time an autorefresh request is issued, the SDRC can service the autorefresh using any of the following commands:

- Single autorefresh command

- Burst of four autorefresh commands
- Burst of eight autorefresh commands

When a burst of four or eight is selected, the programmed period value is automatically scaled in hardware by 4 or 8. Consequently, the value to be programmed does not depend on the selected burst length.

#### 11.2.4.4.8 System Power Management

Unlike the SMS, the SDRC can be configured only in smart-idle mode by setting the SDRC.SDRC\_SYSCONFIG[4:3] IDLEMODE field to 0x2. Once all asserted output interrupts are acknowledged, the SDRC goes into idle state after it receives the request from the PRCM module.

The SDRC acknowledge is conditioned by the internal activity of the SDRC.

---

**NOTE:** As soon as the SDRC goes out of idle state, stalled accesses can be accepted and processed:

- In SDR mode, the access can be immediately processed (unstalled).
  - In DDR fixed delay mode, the accesses is processed (unstalled) after expiration of MODEFIXEDEDELAYINITLAT.
- 

#### 11.2.4.4.9 Power-Saving Features

In the SDRC there are three ways to save power and they can be applied simultaneously:

- Page opening/closure policy
- Dynamic low-power mode
- Static low-power mode

##### 11.2.4.4.9.1 Page Opening/Closure Policy

The OMAP device supports only one page policy. The SDRC.SDRC\_POWER\_REG[0] PAGEPOLICY bit must be set to 1.

The SDRC tracks open pages, if any, and determines whether the current access is to an open or a closed page. If the accessed page is open, the SDRC executes the access immediately. The SDRC performs the following procedure:

1. If the current page is already open on this bank the SDRC automatically issues a *precharge* command to close that bank.
2. Opens the accessed page by issuing an *active* command to that bank
3. Executes the access by issuing a *read* or *write* command

Up to four pages can be open simultaneously with a limit of one page per bank. The pages remain open until one of the following occurs:

- New read or write request to another page in the same bank
- Autorefresh request (a *precharge all* command is issued first)
- Self-refresh entry request (a *precharge all* command is issued first)
- Manual *precharge all* command

##### 11.2.4.4.9.2 Dynamic Low-Power Operating Modes

The dynamic low-power operating modes of the SDRC are designed to:

- Control the external SDRAM clock(s)
- Control the internal clock gating of the SDRC when the interconnect interface is idle
- Control the self-refresh functionality

The external SDRAM is controlled through the SDRC.[SDRC\\_POWER\\_REG\[3\]](#) EXTCLKDIS and SDRC.[SDRC\\_POWER\\_REG\[2\]](#) PWDENA bits. The EXTCLKDIS bit is used to disable the external clock when no access is ongoing on the memory interface, whereas the PWDENA bit is used to activate the power-down mode of the target memory by pulling the relevant CKE low each time the memory interface is idle.

When the PWDENA bit is enabled but the EXTCLKDIS bit is not enabled, the SDRC still provides a free-running clock to the external memories: clock gating is done internal to the memory component for power savings.

EXTCLKDIS should be modified only when no access is in progress on the SDRAM interface. Software control is required to make sure the interface is idle.

CKE is dynamically controlled based on the current memory command. There is a zero-latency penalty when this mode is enabled.

The SDRC has three modes of automatic internal clock-gating behavior when the interconnect interface is idle, that is. there are no outstanding active transactions in progress. These modes are controlled through the SDRC.[SDRC\\_POWER\\_REG\[5:4\]](#) CLKCTRL and SDRC.[SDRC\\_POWER\\_REG\[23:8\]](#) AUTOCOUNT fields.

- Mode 0: The autclock gating feature is disabled. No internal clock gating is performed in the SDRC in response to the detection of an idle state on the interconnect interface.
- Mode 1: A 16-bit counter starts decrementing when an interconnect idle condition is detected. The counter start value is loaded from the AUTOCOUNT 16-bit field. When this counter times out, internal clock gating within the SDRC is enabled.
- If an interconnect active command is received before the counter times out, or if an internal autorefresh request is issued, the procedure is aborted, the counter stops decrementing, and the request is serviced immediately.
- Mode 2: This mode is similar to mode 1, but before the internal clock gating, the SDRC places the SDRAM into self-refresh mode and turns off the external SDRAM clock. This is the lowest power mode.

To achieve maximum power savings, TI recommends the use of the PWDENA-, EXTCLKDIS-, and CLKCTRL-related features.

[Table 11-103](#) explains the different power-saving configurations that can be programmed with the SDRC.[SDRC\\_POWER\\_REG\[3\]](#) EXTCLKDIS, SDRC.[SDRC\\_POWER\\_REG\[2\]](#) PWDENA, and SDRC.[SDRC\\_POWER\\_REG\[5:4\]](#) CLKCTRL bits.

**Table 11-103. Dynamic Power Saving Configurations**

CLKCTRL	EXTCLKDIS	PWDENA	CKE	External SDRC CLK <sup>(1)</sup>	SDRAM State	Latency When Exiting Power Mode
0	0	0	Always high	Always on	Keep previous state	
0	0	1	Low when no access	Always on	Power-down	Zero-latency penalty
0	1	0	Always high	Off when no access	Keep previous state	
0	1	1	Low when no access	Off when no access	Power-down	One cycle penalty
1	0	0	Always high	Always on	Keep previous state	
1	0	1	Low when no access	Always on	Power-down	Zero-latency penalty
1	1	0	Always high	Off when no access	Keep previous state	
1	1	1	Low when no access	Off when no access	Power-down	One cycle penalty
2	0	0	Low when no access	Off when no access after AUTOCOUNT expiration	Enter self-refresh after AUTOCOUNT expiration	

<sup>(1)</sup> EXTCLK can be set to 1 all the time for power optimization purposes, except when manual commands are sent. In this case, users must set EXTCLKDIS to 0 to ensure that a clock signal is provided to the memory device.

**Table 11-103. Dynamic Power Saving Configurations (continued)**

CLKCTRL	EXTCLKDIS	PWDENA	CKE	External SDRC CLK <sup>(1)</sup>	SDRAM State	Latency When Exiting Power Mode
2	0	1	Low when no access	Off when no access after AUTOCOUNT expiration	Enter self-refresh after AUTOCOUNT expiration	
2	1	0	Low when no access	Off when no access	Enter self-refresh after AUTOCOUNT expiration	
2	1	1	Low when no access	Off when no access	Enter self-refresh after AUTOCOUNT expiration	

**NOTE:** When connected to a DDR memory, the SDRC never gates the clock provided to the DLL components so that the DLL remains locked during these idle modes. This avoids the maximum of 500 clock cycles latency required for relocking the DLL when the DLL clock is switched off.

All settings for the power-saving features are common to the two CSs. When two CSs are used, however, only the accessed CS exits self-refresh or deep-power-down mode.

If the SDRC.SDRC\_POWER\_REG[6] SRFRONIDLEREQ bit is enabled, the SDRC enters self-refresh mode on a hardware idle request from the PRCM. The memory clock is automatically switched off, after which the SDRC sends an acknowledge back to the PRCM. In this situation, the power manager can switch the SDRC clock off. Therefore, if the SDRC is connected to a DDR memory, and if the DLL is enabled and in TrackingDelay mode, the SDRC waits for the lock status bit of the DLL to be asserted before accessing the memory when the system exits the idle state. The WAKEUPPROC bit of the SDRC\_POWER\_REG register enables the SDRC to automatically wait for 500 cycles (DLL relocking maximum time) before accessing the memory instead of using the LOCK signal. These 500 wait cycles are obeyed only when the DLL is set in TrackingDelay mode. For SDR mode and DLL ModeFixedDelay mode, the access is processed immediately. This mechanism is independent of the CLKCTRL field.

**NOTE: DLL Behavior Upon a Warm Reset Assertion:**

Upon a warm reset event, the DLL is disabled and is no longer locked (the SDRC\_DLLA\_CTRL[3] ENADLL and SDRC\_DLLA\_STATUS[2] LOCKSTATUS bits are reset). The input clock runs at low frequency. To prevent the DLL from remaining unlocked, the software must re-enable the DLL by setting the ENADLL bit to 1. Then, after a maximum of 500 cycles latency required to relock it, the DLL is locked (LOCKSTATUS bit = 1). Thus, the DLL is locked on the stable input clock and, therefore, ready to process incoming requests so that the SDRC can again access the memory.

#### 11.2.4.4.9.3 Static Low-Power Operating Modes

The software-driven controls for low-power operation modes include:

- Possibility to put the memory in self-refresh using the manual command register (SDRC.SDRC\_MANUAL\_p (where p = 0 or 1 for SDRC CS0 or CS1). Each CS can be controlled independently. If both CSs are in self-refresh, the external SDRAM clock can be switched off by setting the SDRC.SDRC\_POWER\_REG[3] EXTCLKDIS control bit to 1. Self-refresh can be exited automatically if an access is initiated onto the CS. Only DPD must be exited manually.
- Possibility to put the memory in deep-power-down mode, if supported by the SDRAM, using the manual command register. Each CS can be controlled independently. The external SDRAM clock can be switched off if both CSs are either in self-refresh or deep-power-down mode by setting the SDRC.SDRC\_POWER\_REG[3] EXTCLKDIS control bit to 1. Another manual command must be used for the memory to exit deep-power-down mode. After a memory exits from that mode all data are lost, and a full initialization sequence must be sent to the device, before it can be used.

#### 11.2.4.4.10 SDR Power-Down Mode

In some applications, the SDRC power domain can be powered down while the external memory is in self-refresh mode.

When the SDRC is powered off, an isolation stage prevents an unwanted exit from self-refresh when the context is restored. SDRC outputs that control the SDRAM are set to maintain self-refresh or deep-power-down (CKE low).

When a reset occurs, the default reset state of the SDRC is power-down enable (PDE).

When exiting the off mode:

- Power is restored to the SDRC.
- The software reconfigures all registers. If the NOMEMORYMRS bit is set, the MR and EMR registers can be set through the SDRC.SDR\_C\_MR\_p and SDRC.SDR\_C\_EMR2\_p registers (see [Section 11.2.4.5, Mode Registers](#)).
- Exit from self-refresh mode is achieved through the SDRC.SDR\_C\_MANUAL\_p CMDCODE field. Because exit from the self-refresh field is unconditional (that is, the current state of the SDRC state-machine is not considered), ensure that autorefresh is disabled.

Once the context is successfully restored, the software can reinitialize the SDRAM or return the SDRAM to self-refresh. When the device successfully exits self-refresh, autorefresh must be re-enabled.

#### 11.2.4.4.11 Controlled Delay Line

The DLL/CDL module is a hard macro composed of one master delay-locked loop (DLL) and five slave-controlled delay lines (CDL). It is used to generate precise delays suitable for DDR read and write operations. DLL delays are tracked at high frequency on process dispersion, and voltage and temperature variations (PVT) .

A CDL is a component with a clock input signal, a clock output signal, and a delay value input. The output signal is the input signal delayed according to the delay value.

The DLL output is a command that controls the CDLs (plus the controlled voltage) and assures an output signal with 90-degree delay with respect to its input signal. The DLL contains five CDL blocks.

##### 11.2.4.4.11.1 Purpose of the DLL/CDL Module

In DDR applications, the DLL and CDL combination helps provide a data strobe (DQS) with a delay suitable to the main read and write RAM operations that exceed 83 MHz. The DLL functions within a locking range of 83 to 166 Mhz. Below 83 MHz, the DLL must be used in unlocked mode. For lower clock frequencies, set the DLL to bypass mode.

DLL/CDL is used to delay the incoming DQS in case of DDR read, or delay the output DQ (data lines) in case of DDR write (and, hence, to increase the ac timing margin). DQS is used only with DDR memory. There is no need to use the DLL/CDL for the SDR DRAM because data is strobed every clock cycle. The DQS signals are left unconnected for SDR SDRAM memories.

DQS is propagated with the data (thus reducing the impact of the propagation delay) and is used by the receiver to sample the data.

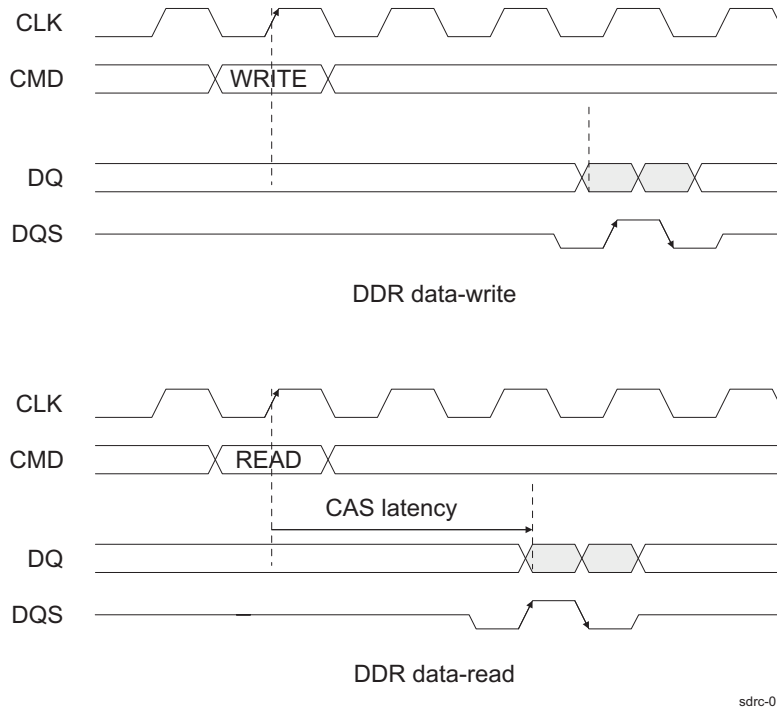

The DLL/CDL combination minimizes the negative effects caused by skews and jitters of clock signals. The delay introduced by the CDL base unit depends on PVT conditions. Moreover, the CDL timing delay is not a linear function of the DLL counter offset. By means of the DLL feedback loop, the delay value is updated in real time and is adjusted according to voltage and temperature variations.

DDR interfaces transmit data on both edges of the DQS bidirectional data strobe. Address and control signals transmit at half the data frequency (that is, at the DDR clock frequency) and latch only on the rising edge of the transmit clock.

The bidirectional data strobe (DQS) is transmitted externally, along with data, for use in data capture at the receiver. `sdrc_dqs[3:0]` is an SDRC I/O that connects the SDRC with DDR SDRAM DQS pins. See [Figure 11-43](#) for an overview of DDR SDRAM connection with the SDRC. DQS is transmitted by the DDR SDRAM during reads and by the SDRC during writes. DQS is edge-aligned with data for reads and center-aligned with data for writes, as shown in [Figure 11-57](#). Another DDR write path can be selected with the `WRITEDDRCLKX2DIS` bit of the `SDRC_DLLA_CTRL` register. This path uses a double frequency input clock coming from the PRCM to achieve proper generation of MDDR write data bytes, center-aligned with the corresponding DQS lines. It is recommended to set the `WRITEDDRCLKX2DIS` bit to 0 to use this path.

[Figure 11-57](#) shows the generic DDR data-write and data-read waveforms.

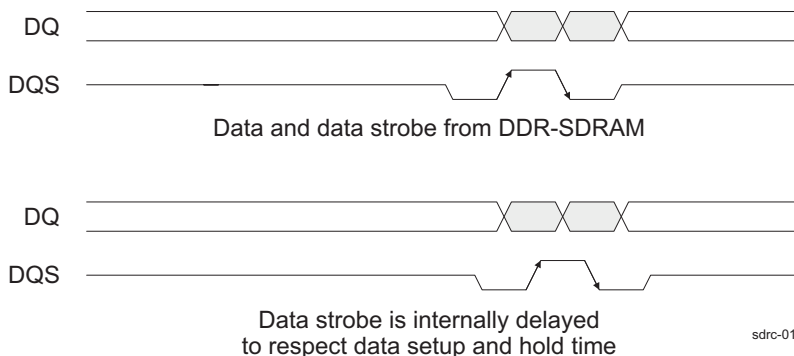

**Figure 11-57. Generic DDR Data-Write and Data-Read Waveforms**

sdrc-014

[Figure 11-58](#) shows the DDR SDRAM data and data strobe DQS signals exiting synchronously and in phase during a data read. DQS signals are used to sample incoming data internally and, hence, must be delayed to create data-setup and data-hold time at the synchronization flip-flop inputs, as shown in the bottom waveforms of [Figure 11-58](#). This is the goal of the DLL/CDL module.

**Figure 11-58. Required Synchronization DFF Input Signals**

sdrc-015

11.2.4.4.11.2 DLL/CDL Module Architecture

Figure 11-59 shows how the DLL/CDL interacts with the synchronization flip-flops. See Table 11-102 for more information on device pins and SDRC data-lane configurations regarding DQS.

Figure 11-59. DLL/CDL Architecture

sdrc-016

Figure 11-60 shows a simplified block diagram of the DLL/CDL module.

**NOTE: PASR Setting Before Entering Self-Refresh Mode:**

Partial array self-refresh (PASR) allows memory accesses to all banks when the attached memory is not in self-refresh. Software must ensure that after a self-refresh mode with PASR field enabled on banks, only accesses to the refreshed parts of the memory are performed. Failure to do so may result in fetching corrupted data.

## 11.2.5 SDRC Subsystem Basic Programming Model

This section contains programming guides on setting up the SMS and SDRC registers according to the required application.

### 11.2.5.1 SMS Basic Programming Model

#### 11.2.5.1.1 SMS Firewall Usage

Because region 0 always has level 0 priority, it can be masked by any protected region.

To configure a region:

1. Set the SMS.SMS\_RG\_ATT<sub>i</sub> register (where i is the region index from 0 to 7).
2. Set the SMS.SMS\_RG\_RDPERM<sub>i</sub> register.
3. Set the SMS.SMS\_RG\_WRPERM<sub>i</sub> register.
4. Set the SMS.SMS\_RG\_START<sub>j</sub> register (except for region 0. j is the region index from 1 to 7).
5. Set the SMS.SMS\_RG\_END<sub>j</sub> register (except for region 0. j is the region index from 1 to 7).

Region 0 is always active. There are no start and an end address for region 0. As soon as the SMS.SMS\_RG\_START<sub>j</sub>[30:16] STARTADDRESS and SMS.SMS\_RG\_END<sub>j</sub>[30:16] ENDADDRESS registers (where j = 1 to 7) are programmed, the firewall is activated. To prevent unexpected violations, ensure that the protection regions do not overlap.

Region 1 ensures the proper dynamic programming of protection for regions 2 through 7. For example, the protected region A is set and currently accessed, but it must be enlarged. To avoid deactivating region A and exposing its content to unwanted leakage, region 1 can be used to mask this whole area during reprogramming. When region A is correctly reprogrammed, region 1 can be deactivated.

When all the required regions are programmed, the locking mechanism allows freezing the configuration, thus ensuring no further reprogramming.

#### 11.2.5.1.2 VRFB Context Configuration

Using the RE requires several initialization programming steps. After an RE context is set up, an application can use it transparently, as if addressing a frame buffer object with a standard raster-based memory arrangement.

1. Define the page configuration. This operation usually depends only on the external memory device. The same page settings are then applied to any newly created rotated frame buffer.

Consider an SDRAM device with 1024-byte pages. The page can be defined as a 16 x64 array. The page is not necessarily a square (32 x32 is also a suitable value). It is recommended that the longest side corresponds to the access direction requiring the maximum bandwidth.

In terms of register settings, in any context that uses that page size:

Page (page) width =  $2^{pw}$  bytes (that is, pw = 6)

Page (page) height =  $2^{ph}$  rows (that is, ph = 4)

2. The application must allocate the appropriate amount of memory in the SDRAM address space, as required by the size of the frame buffer object.

*Example: Create a 400 x300 frame buffer, 16 bits per pixel*

- Pixel size =  $2^{ps}$  bytes (that is ps = 1)
- Number of pages per line:  $400 \times 2 / 64 = 12.5$ , rounded up to 13
- Number of pages per column:  $300 / 16 = 18.75$ , rounded up to 19

In terms of register settings, the image size parameters correspond to the enlarged image, and are programmed to:

- Image width =  $w$  pixels (that is,  $w = 13 \times 64 / 2 = 416$ )
- Image height =  $h$  pixels (that is,  $h = 19 \times 16 = 304$ )

---

**NOTE:** In this example, the values obtained are not integer values, but are rounded up to the closest integer value. This results in a loss of physical memory, generally negligible compared to the total size of the image.

---

In terms of memory allocation (in the physical memory), this corresponds to a  $416 \times 304 \times 2 = 252,928$ -byte buffer.

The physical base address of this buffer must be aligned on a page boundary (in that example, a 1024-byte boundary; that is, the 10 LSBs of the base address must be all zeros). This buffer must be allocated as a contiguous memory segment.

All these parameters, once determined, must be loaded in the registers of the chosen context (there are 12 VRFB contexts with 12 independent sets of registers).

*Example, context 1:*

- Configure the physical base address of the frame buffer. Example: 512M bytes, start of CS0, SMS.SMS\_ROT\_PHYSICAL\_BAn[30:0] PHYSICALBA = 0x20000000 (where  $n = 1$ )
  - Configure the image height and width:  
Image width (416): SMS.SMS\_ROT\_SIZE $n$ [10:0] IMAGEWIDTH = 0x1A0 (where  $n = 1$ )  
Image height (304): SMS.SMS\_ROT\_SIZE $n$ [26:16] IMAGEHEIGHT = 0x130
  - Configure the control parameters:  
Pixel size (example: 2 bytes,  $2^1$  bytes): SMS.SMS\_ROT\_CONTROL $n$ [1:0] PS = 0x1 (where  $n = 1$ )  
Page (page) size (example: 1024 bytes = 64 bytes  $\times$  16 bytes)  
Page height (example: 16 rows,  $2^4$  rows): SMS.SMS\_ROT\_CONTROL $n$ [10:8] PH = 0x4  
Page width (example: 64 bytes,  $2^6$  bytes): SMS.SMS\_ROT\_CONTROL $n$ [6:4] PW = 0x6
3. The frame buffer just created is now ready for use by the different system initiators (MPU, sDMA, LCD controller, etc.).

From the perspective of these modules, the frame buffer object can be accessed at the following VRFB address-space memory locations:

- Context 1 0-degree view: 0x7400 0000
- Context 1 90-degree view: 0x7500 0000
- Context 1 180-degree view: 0x7600 0000
- Context 1 270-degree view: 0x7700 0000

The start address of the view corresponds to the logical origin of the image ( $x = 0$ ,  $y = 0$ ). The image pitch parameter, commonly defined as the distance between two vertically adjacent pixels, is fixed to 2048 pixels.

*Example of usage by the application:*

In a system using an 400  $\times$  300 LCD panel that has a native landscape orientation, the natural scan order is as shown in [Figure 11-61](#).

**Figure 11-61. Natural Scan Order**

sdr-018

The display buffer is the one created in the example sequence.

When the application is running and uses the portrait orientation for the display (typically, a PDA-type application):

- The LCD controller accesses the frame buffer using the 0-degree view.
- The processor and other initiators, such as 2D DMA or 3D accelerators, use the 90-degree view.

When the application is running and uses the landscape orientation for the display (typically, a video recorder/player or gaming application):

- The LCD controller still accesses the frame buffer using the 0-degree view.
- The processor and other initiators, such as 2D DMA or 3D accelerators, also use the 0-degree view. See [Section 11.2.6.1.1](#).

### 11.2.5.1.3 Memory-Access Scheduler Configuration

The memory-access scheduler is configured as follows:

- For each of the three classes, the arbitration parameters are:
  - SMS.SMS\_CLASS\_ARBITER0 through SMS.SMS\_CLASS\_ARBITER2
    - One high-priority FIFO queue in the class (HIGHPRIOVECTOR field)
    - Number of consecutive transactions to perform (EXTENDEDGRANT field)
    - Burst transaction submitted for arbitration immediately or after the burst has been buffered (BURST-COMPLETE field)

### 11.2.5.1.4 Error Logging

All data transfers in the SMS are full handshake. The SMS uses this capability to signal the system when a transaction error is detected.

The SMS captures the address of the faulty access in the SMS.SMS\_ERR\_ADDR register. The error type is logged in the SMS.SMS\_ERR\_TYPE register. Once a faulty access is logged and the SMS.SMS\_ERR\_TYPE[0] ERRORVALID bit is set, the next faulty accesses cannot be logged before clearing the ERRORVALID bit.

In the case of an interconnect transaction, an error response is generated if any of the following occur:

- An incoming request arrives after an idle request from the PRCM.
- An illegal command is received.
- A protection region overlap is detected.
- Protection errors.

It is assumed that the system interconnect on which the SMS is plugged is responsible for signaling the error event to the host MPU based on the interconnect response. The MPU error handler can then consult the error logging registers.

## 11.2.5.2 SDRC Configuration

### 11.2.5.2.1 IP Revision

The IP revision code can be read in the SDRC.[SDRC\\_REVISION](#)[7:0] REV field.

### 11.2.5.2.2 Reset Behavior

The reset behavior of the SDRC can be classified into three subgroups:

- Asynchronous cold-reset (power-on reset) behavior
- Asynchronous warm reset behavior
- Synchronous soft-reset behavior

When the system-wide power-on reset is applied through cold reset, all flops are reset to their default values, and all state-machines are returned to their idle states.

The programming model for data recovery following a warm reset is as follows:

- Program the SDRC.[SDRC\\_POWER\\_REG](#) register to enable the SDRC.[SDRC\\_POWER\\_REG](#)[7] SRFONRESET bit.

A warm reset condition is then issued.

- The SDRC enters self-refresh mode since the SRFONRESET bit is set.
- The SDRC does not execute global SDRC reset since the reset is not qualified as cold.
- The SDRC state-machine maintains the external memory device in self-refresh.

The first SDRC access to the configuration register must then be:

1. Check the SDRC configuration.
2. Exit self-refresh mode using the manual command register.

A software-controlled reset is also available by using the SDRC.[SDRC\\_SYSCONFIG](#)[1] SOFTRESET bit (set this bit to 1 to activate the reset). The completion of the reset can be determined by reading the SDRC.[SDRC\\_SYSSTATUS](#)[0] RESETDONE bit.

When the SDRC is reset due to the presence of either a soft or cold reset, all SDRC flops are reset.

---

**NOTE:** **SDRC Requirement at First Power-Up to Have `sdr_cke` Pin High**

To comply with the JEDEC standard, `sdr_cke` pins values are forced to 1 during the initial memory power-up phase: software must ensure that `sdr_cke` pin is released after the initialization phase; it happens only at first power-up (on a cold reset). Thus, at the end of the initial SDRC power-up sequence and before programming the PWDENA field, software must ensure that the `sdr_cke` pin is driven by the SDRC module. Then the value of the PWDENA field can be modified. See [Section 11.2.5.4.1](#) for more details on `sdr_cke` driving.

---

---

**NOTE:** Set the INPUTENABLE0 bit of CONTROL.CONTROL\_PADCONF\_SDRCLK to assure the synchronization of `sdr_clk`. For more information, see [Chapter 7, System Control Module](#).

---

### 11.2.5.3 SDRC Setup

A number of device parameters must be set before executing the initialization sequence.

#### 11.2.5.3.1 Chip-Select Configuration

CS0 always starts at 0x8000 0000 (with respect to the 32-bit interconnect address). There is no restriction on the presence of any SDRAM on CS0 or CS1.

The total address space of the SDRC is 1G byte/8G bits. The total address space is divided into 8 x128M-byte partitions as shown in [Figure 11-51](#). Each partition is a possible start address for CS1, except for the partition occupied by CS0.

The start address for CS1 is defined by the SDRC.SDR<sub>C</sub>\_CS\_CFG[9:8] CS1STARTLOW and SDRC.SDR<sub>C</sub>\_CS\_CFG[3:0] CS1STARHIGH fields.

Space 0, selected by the SDRC using the CS0 (nCS0) output pin, is always at offset 0 from the SDRAM memory space base address. The size of this area is programmable through the SDRC.SDR<sub>C</sub>\_MCFG\_p[17:8] RAMSIZE field, where p = 0. Space 1, selected by the SDRC using the CS1 (nCS1) output pin, is at an offset from the SDRAM memory space base address; this offset is programmable in 128M-byte increments. The size of this area is programmable through the SDRC.SDR<sub>C</sub>\_MCFG\_p[17:8] RAMSIZE field, where p = 1. The type of device for each area is programmable through the SDRC.SDR<sub>C</sub>\_MCFG\_p register (where p = 0 or 1 for SDRC CS0 or CS1).

---

**NOTE:** Ensure that space 0 and space 1 do not overlap each other or extend farther than the maximum 1G-byte SDRC memory space, as explained in [Section 2.2, Global Memory Space Mapping](#), of [Chapter 2, Memory Mapping](#).

---

#### 11.2.5.3.2 Memory Configuration

The memory configuration is defined on a per-CS basis through the SDRC.SDR<sub>C</sub>\_MCFG\_p register (where p = 0 or 1 for SDRC CS0 or CS1).

[Table 11-104](#) lists the memory configuration.

**Table 11-104. Memory Configuration**

Bit Field	Comments
ADDRMUXLEGACY	Address multiplexing scheme
RAMSIZE	Defines the physical RAM address space in terms of 2M -byte chunks
B32NOT16	External device data bus width.
DEEPPD	Set this bit if the memory supports deep-power-down mode. (This bit is only a flag for software. It does not affect any SDRC function.)
DDRTYPE	Mobile DDR
RAMTYPE	Single Data Rate or Double Data Rate SDRAM

---

**NOTE: Exported Register Reset Values and Lock Bit**

The reset values of SDRC.SDR<sub>C</sub>\_MCFG\_p and SDRC.SDR<sub>C</sub>\_SHARING are exported in the control module. At reset, these registers take the value previously stored in the control module. A new bit is added to each register to provide the capability to lock these three registers into read-only accesses:

- SDRC.SDR<sub>C</sub>\_MCFG\_p[30] LOCKSTATUS bit (p = 0 or 1 for CS0 or CS1)
- SDRC.SDR<sub>C</sub>\_SHARING[30] LOCK bit

The reset value of each lock bit is also imported from the control module.

---

### 11.2.5.3.3 SDRAM AC Timing Parameters

The AC parameters described in [Table 11-105](#) can be independently programmed (standard JEDEC LPDDR1 terminology is used here) in clock cycles for each of the two memory areas through registers `SDRC.SDRC_ACTIM_CTRLA_p` and `SDRC.SDRC_ACTIM_CTRLB_p` ( $p = 0$  or  $1$ , depending on the CS area).

**Table 11-105. Programmable AC Parameters**

SDRC AC Parameter	Description	Range (Clock Ticks)
tRFC	AUTO REFRESH to ACTIVE / AUTO REFRESH command period (autoReFresh Cycle time)	0 - 31
tRC	ACTIVE to ACTIVE command period (Row Cycle time)	0 - 31
tRAS	ACTIVE to PRECHARGE command period	0 - 15
tRP	PRECHARGE command period (Row Precharge time)	0 - 7
tRCD	ACTIVE to READ or WRITE delay (Row-to-Column Delay time)	0 - 7
tRRD	ACTIVE bank A to ACTIVE bank B delay	0 - 7
tWR	WRITE Recovery time (also known as tDPL)	0 - 7
tDAL	Auto precharge write recovery + precharge time	0 - 31
tWTR	Internal Write to Read command delay (also known as tCDLR)	1 - 3
tCKE	CKE min pulse width (high and low pulse width)	1 - 7
tXP	Exit Power-Down to next valid command delay	1 - 7
tXSR	Self-Refresh exit to next valid command delay	0 - 255

Example of configuration:

If there is a minimum tRC requirement of 88 ns at 100 MHz,  $88/10 = 9$  (8.8 is rounded up). Therefore, nine clock cycles must be set.

The SDRC AC parameters described in [Table 11-106](#) are hard-coded.

**Table 11-106. Nonprogrammable AC Parameters**

SDRC AC Parameter	Description	Range (Clock Ticks)	Comment
tMRD	MODE REGISTER SET command period	3	
tDQSS	Write command to first DQS latching transition	1 (0.75 - 1.25 CK)	
tRPRE	Read preamble	1 (0.9 - 1.1 CK)	DQS is held low for read when driving on the same cycle as the read command is stopped.

**NOTE:** The SDRC uses tXSR only when exiting self-refresh mode, regardless of the first command issued. The SDRC systematically inserts an autorefresh command before it serves the first request.

### 11.2.5.3.4 DLL/CDL Configuration

The DLL unit is configured by writing to the `SDRC.SDRC_DLLA_CTRL` register. This register contains the following fields:

- FIXEDDELAY
- MODEFIXEDDELAYINITLAT
- WRITEDDRCLKX2DIS
- DLLMODEONIDLEREQ

- DLLIDLE
- ENADLL
- LOCKDLL
- DLLPHASE

To support low-frequency DDR access, set the DLL in fixed delay mode by setting the [SDRC\\_DLLA\\_CTRL](#) [2] LOCKDLL bit to 0x1. In this mode, the [SDRC\\_DLLA\\_CTRL](#) [31:24] FIXEDELAY field allows the programming of the CDL delay. This provides the correct fixed DCB code based on the input frequency. Only the voltage precharge part of the DLL is still used to control the CDL instances in this mode, but the control loop is broken and the voltage control is inactive.

When fixed delay mode is enabled, a counter (programmable through the [SDRC\\_DLLA\\_CTRL](#) [23:16]MODEFIXEDELAYINITLAT field) based on the input frequency allows the SDRC to stall all incoming requests. Once this counter expires, the SDRC starts accessing the memory. The DLL characterization shows that this feature is not useful and that this value shall be set to 0x0, leading actually to a null delay.

WRITEDDRCLKX2DIS controls which clock is used for the write data path. The WRITEDDRCLKX2DIS bit ensures the proper MDDR write data bytes by using a double frequency input clock coming from the PRCM module.

The DLL can be put in idle mode using the [SDRC\\_DLLA\\_CTRL](#)[4] DLLIDLE bit. When in idle mode, the DLL lock is lost. The precharge voltage is kept stable to enable faster relock when going back to a functional state. If set, this bit overrides the ENADLL bit. Thus, avoid completely powering down the DLL by keeping the precharge voltage and cutting off the analog loop. Exiting from this idle mode saves some clock cycles compared to exiting from power-down mode. Refer to the note (DLL behavior upon a warm reset assertion) in [Section 11.2.4.4.9.2, Dynamic Low-Power Operating Modes](#)). Furthermore, the [SDRC\\_DLLA\\_CTRL](#)[6:5] DLLMODEONIDLEREQ field defines the modes (power-down/DLLIDLE/No action) of the DLL that are automatically entered upon an Idle\_req assertion. The DLL mode (TrackedDelay or ModeFixedDelay mode) is updated only when Idle\_req/Idle\_ack handshake protocol occurs, warm reset occurs, PWRDN is enabled, or DLLIDLE mode enabled. Power-down mode is asserted upon warm reset assertion. If power-down and DLLIDLE are asserted simultaneously, power-down overwrites DLLIDLE mode inside the DLLCDL cell.

To modify the SDRC input clock when the DLL is locked and active, the DLL must first enter either its idle mode or its power-down mode. The SDRC input frequency can be changed by using any of the following scenarios:

- Internal signals handshaking protocol with PRCM module
- Warm reset event
- DLLIDLE mode
- Power-down mode

The ENADLL bit controls the PWRDN mode of the DLL module.

The LOCKDLL bit sets the DLL in TrackedDelay (lock) or ModeFixedDelay (unlock) mode. ModeFixedDelay mode is supported up to 83 MHz.

The DLLPHASE control bit is used to set up the nominal delay tracked by the DLL. See [Section 11.2.4.4.11, Controlled Delay Line](#), for more information about the CDL/DLL module.

DLLMODEONIDLEREQ is of no importance to the Idle\_ack generation. In case DLLMODEONIDLEREQ = 2 and Idle\_req occurs, Idle\_ack can be generated and SDRC/core can go to idle; however, recovery from this state may be incorrectly performed and the DLL cannot relock. If this happens, the only solution to recover is to disable and then re-enable the DLL. DLLMODEONIDLEREQ = 2 is not a valid configuration under Idle\_req assertion and must not be used. DLLMODEONIDLEREQ can be set 0 or 1, depending on whether the priority is shorter wake-up latency or lower power consumption.

### 11.2.5.3.5 Mode Register Programming and Modes of Operation

The SDRC contains a group of registers known as the memory mode registers. These registers define the operational modes of the target SDRAM.

- MR: Mode register used to define operational parameters common to SDR and DDR SDRAMs.

- EMR1: Extended mode used to define operational parameters exclusive to DDR SDRAM (irrelevant to the SDRC since regular DDRs are not supported).
- EMR2: Extended mode used to define operational parameters exclusive to mobile SDRAM.

#### 11.2.5.3.5.1 Mode Register (MR)

The 12-bit SDRC.[SDRC\\_MR\\_p](#) register (p = 0 or 1 for CS0 or CS1) is common to all SDR and DDR SDRAMs and controls the following parameters:

- Write burst mode
- CAS latency
- Serial/interleaved mode
- Burst length

When programming the SDRC.[SDRC\\_MR\\_p](#) bit fields (where p = 0 or 1 for SDRC CS0 or CS1), consider the following:

- CAS latencies of 1, 2, 3, 4, and 5 are supported (CASL).
- Only serial mode (not interleaved mode) is supported (SIL = 0x0).
- A burst length of 2 is supported for SDR SDRAM (BL = 0x2).
- A burst length of 4 is supported for DDR SDRAM (BL = 0x4).
- Burst lengths of 1 (BL = 0x0), 8 (BL = 0x3), and full page (BL = 0x7) are not supported.

Writing to SDRC.[SDRC\\_MR\\_p](#) initiates an implicit Load Mode register command qualified by BA1, BA0 = 0,0 except if the NOMEMORYMRS bit is set.

#### 11.2.5.3.5.2 Extended Mode Register 2 (EMR2)

The SDRC.[SDRC\\_EMR2\\_p](#) register (p = 0 or 1 for CS0 or CS1) is specific to mobile SDRAM devices. It is a 12-bit register that controls the following standard parameters:

- Partial Array Self-Refresh (PASR)
- Temperature Compensated Self-Refresh (TCSR)
- Driver Strength (DS)

The SDRC.[SDRC\\_EMR2\\_p](#)[2:0] PASR field programs the partial array self-refresh feature. The low power SDR SDRAM granularity is much finer than the granularity available in a mobile DDR SDRAM. The SDRC.[SDRC\\_EMR2\\_p](#)[4:3] TCSR field programs the temperature compensated self-refresh feature. The TCSR granularity available in a low power SDR is much finer than the granularity available in a mobile DDR.

Writing to SDRC.[SDRC\\_EMR2\\_p](#) initiates an implicit load mode register command qualified by BA1, BA0 = 1,0 except if [SDRC\\_SYSCONFIG](#)[8] NOMEMORYMRS is set.

#### 11.2.5.3.6 Autorefresh Management

The SDRAM refresh configuration register group controls refresh management in normal operation. This group contains two SDRC.[SDRC\\_RFR\\_CTRL\\_p](#) registers that are defined on a per-CS basis and contain the following bit fields:

- SDRC.[SDRC\\_RFR\\_CTRL\\_p](#)[1:0] ARE (where p = SDRC CS value 0 or 1)
- SDRC.[SDRC\\_RFR\\_CTRL\\_p](#)[23:8] ARCV (where p = SDRC CS value 0 or 1)

These bit fields can enable and disable autorefresh. Autorefresh bursts of 1, 4, and 8 are programmed using these fields. The autorefresh burst starts when the 16-bit autorefresh counter decrements to 0. The ARCV field loads the autorefresh counter with a 16-bit autorefresh value. The ARCV value is calculated using the following formula:

Refresh value = (refresh interval / clock period / number of rows) - margin

**Note:** Memory refresh interval in time unit. Margin is 50 (cycles).

The margin considers the possibility of an ongoing access when the counter expires, thus delaying the effective refresh sequence.

The value to be programmed is independent of the burst-refresh configuration: if a burst-refresh is configured, the value is automatically scaled in hardware to the burst-refresh size.

Autorefresh is enabled by programming the SDRC.SDRC\_MANUAL\_p[3:0] CMDCODE field to 0x2 (where p = 0 or 1 for SDRC CS0 or CS1).

### 11.2.5.3.7 Page Closure Strategy

The page closure strategy is defined on a per-bank basis by setting the SDRC.SDRC\_POWER\_REG[0] PAGEPOLICY bit. SDRC defines one type of page closure strategy:

1. High power/high bandwidth: Bandwidth consumption is critical.

The SDRC tracks open pages. The SDRC determines whether the current access is an open page or a closed page. The SDRC does the following:

1. If the current page is already open on this bank the SDRC automatically issues a *precharge* command to close that bank.
2. Opens the accessed page
3. Executes the access

In the worst case, four pages (one page per bank) may be opened simultaneously.

The PAGEPOLICY bit must be set to 1 to enable this mode.

### 11.2.5.4 Manual Software Commands

The manual commands register SDRC.SDRC\_MANUAL\_p (where p = 0 or 1 for SDRC CS0 or CS1) is used to implement software-driven commands:

- NOP command
- Precharge All command
- Autorefresh command
- Enter deep-power-down command
- Exit deep-power-down command
- Enter self-refresh command
- Exit self-refresh command
- Set CKE high command
- Set CKE low command

These commands are described in the following section:

- NOP (CMDCODE: 0x0)

When the SDRC.SDRC\_MANUAL\_p[3:0] CMDCODE field is programmed with 0x0, the SDRC issues a NOP/inhibit command. The following table lists the status of the SDRC memory port signals.

NOP does not initiate any new operation, but it is needed to complete operations that require more than a single clock cycle-like autorefresh.

Inhibit is also a NOP. nCS high disables the command decoder so that nRAS, nCAS, nWE, and all the address inputs are ignored.

Command	nCS	nRAS	nCAS	nWE
Inhibit	H	X	X	X
NOP	0	H	H	H

- Precharge all (CMDCODE: 0x1)  
When the SDRC.[SDRC\\_MANUAL\\_p\[3:0\]](#) CMDCODE field is programmed with 0x1, the SDRC issues a precharge all command. The following table lists the status of the SDRC memory port signals. During the command, address A10 remains high, and bank information (BA0 and BA1) is don't care. All banks can be precharged at the same time by using the precharge all command. At the end of tRP, after performing precharge on all of the banks, they enter the idle state.

Command	A10	nCS	nRAS	nCAS	nWE
Precharge all	H	L	L	H	L

- Autorefresh (CMDCODE: 0x2)  
When the SDRC.[SDRC\\_MANUAL\\_p\[3:0\]](#) CMDCODE field is programmed with 0x2, the SDRC issues an autorefresh command. The following table lists the status of the SDRC memory port signals. In addition to the signal status mentioned below, the CKE signal is at logic high for autorefresh. The autorefresh command can only be asserted when all banks are in idle state and the device is not in power-down mode (CKE is high in the previous cycle). The autorefresh command must be followed by NOPs until the autorefresh operation completes. All banks are in the idle state at the end of the autorefresh operation.

Command	nCS	nRAS	nCAS	nWE
Autorefresh	L	L	L	H

- Enter deep-power-down (CMDCODE: 0x3)  
When the SDRC.[SDRC\\_MANUAL\\_p\[3:0\]](#) CMDCODE field is programmed with 0x3, the SDRC executes an enter DPDM command. This command is used for low-power devices (that is, LPSDR or MDDR devices that support deep-power-down mode). The following table shows the status of the SDRC memory port signals. The device enters deep-power-down mode by having nCS and nWE held at logic low with nRAS and nCAS high at the rising edge of the clock, while CKE is low.

Command	nCS	nRAS	nCAS	nWE	CKE
Enter DPDM	L	H	H	L	L

- Exit deep-power-down command (CMDCODE: 0x4)  
When the SDRC.[SDRC\\_MANUAL\\_p\[3:0\]](#) CMDCODE field is programmed with 0x4, the SDRC executes an exit deep-power-down command. The device exits deep-power-down mode when the inhibit command is sampled with CKE held at logic high.
- Enter self-refresh (CMDCODE: 0x5)  
When the SDRC.[SDRC\\_MANUAL\\_p\[3:0\]](#) CMDCODE field is programmed with 0x5, the SDRC puts the memory into self-refresh. The signal status is the same as defined in autorefresh, and CKE is held at logic low during the self-refresh entry command. The self-refresh mode is entered from the all-banks-idle state by asserting nCS, nRAS, nCAS, and CKE low, and nWE high. Once the self-refresh mode is entered, only the CKE state being low matters; all other inputs, including the clock, are ignored and remain in self-refresh mode.
- Exit self-refresh (CMDCODE: 0x6)  
When the SDRC.[SDRC\\_MANUAL\\_p\[3:0\]](#) CMDCODE field is programmed with 0x6, the SDRC executes the self-refresh exit command and, after meeting the tXSR timing parameter, executes one autorefresh command to adhere to the memory protocol. It is an exit self-refresh command when CKE is detected high with a NOP command. Self-refresh is exited by restarting the external clock and then asserting CKE high. This must be followed by NOPs for a minimum time of tXSR before the SDRAM reaches idle state to begin normal

operation.

- Set the CKE signal high (CMDPCODE: 0x7)  
When the SDRC.[SDRC\\_MANUAL\\_p](#)[3:0] CMDPCODE field is programmed with 0x7, CKE is set to high. An example of where this command is used is during DDR memory initialization.
- Set the CKE signal low (CMDPCODE: 0x8)  
When the SDRC.[SDRC\\_MANUAL\\_p](#)[3:0] CMDPCODE field is programmed with 0x8, CKE is set to low. An example of where this command can be used is to put memory in power-down mode.

#### 11.2.5.4.1 Low-Power SDR/Mobile DDR Initialization Sequence

The initialization sequence is executed after the following occur:

1. Power is applied.
2. The clock is stable.
3. The power-on reset sequence is executed.

The initialization sequence is executed by programming the following manual command registers, in the SDRC.[SDRC\\_MANUAL\\_p](#)[3:0] CMDPCODE bit field, on a per-CS basis:

1. Set CMDPCODE to 0x0 (NOP command), for a minimum delay of 200  $\mu$ s. Another way to stabilize the connected device internal circuits is to deactivate the corresponding CS for the same amount of time.

#### CAUTION

Programmers must ensure that the next command (precharge-all command) is sent after a minimum delay of 200  $\mu$ s. Other timings, such as tRP timing between the precharge-all command and autorefresh command, are handled automatically by the SDRC depending on the timing values programmed in the appropriate registers.

2. Set CMDPCODE to 0x1 (precharge all command) to precharge all banks.
3. Set CMDPCODE to 0x2 (autorefresh command). The autorefresh command is automatically generated after a time of tRP, hence [SDRC\\_ACTIM\\_CTRLA\\_p](#)[17:15] TRP (where p = 0 or 1, for CS0 or CS1) must be programmed as stated in the external memory datasheet.
4. A second autorefresh command must be programmed. Set CMDPCODE to 0x2 another time.
5. Then configure the mode register [SDRC\\_MR\\_p](#) (p = 0 or 1) with BA0 and BA1 set to 0.

Because the mode register powers up in an unknown state, it must be loaded before applying any operational command.

When MR is reprogrammed, a suitable time must elapse before an active command is issued. The hardware ensures this by fixing tMRD to two clock cycles. The SDRC can handle CKE as force on CKE is released through the control module.

After VDD initialization [sdr\\_cke0](#) and [sdr\\_cke1](#) signals are forced outside the SDRC subsystem by the control module. When the external SDRAM device is correctly initialized the control module must release the force on these [sdr\\_cke](#) signals by clearing the corresponding MUXMODE bit fields in [CONTROL.CONTROL\\_PADCONF\\_SAD2D\\_SBUSFLAG](#)[18:16] and [CONTROL.CONTROL\\_PADCONF\\_SDR\\_CKE1](#)[2:0] bit fields for [sdr\\_cke0](#) and [sdr\\_cke1](#) respectively. See [Section 11.2.5.2.2](#) for more information on reset behavior.

#### 11.2.5.4.2 Read/Write Access

The commands required for a normal read/write access are automatically generated as a function of the following:

- The read/write command
- The address bus. A10 defines precharge all
- The relevant [SDRC\\_MR\\_p](#) / [SDRC\\_EM2\\_p](#) registers

### 11.2.5.4.3 Memory Power Management

#### 11.2.5.4.3.1 Clock Enable Management

The SDRC supports two autonomous clock enable pins CKE0 and CKE1. Each CS (CS0 or CS1) has its own CKE signal. Power management of the CS0 memory is controlled by CKE0. Power management of the CS1 memory is controlled by CKE1. This allows the SDRAM memories associated with CS0 or CS1 to be independently placed in power-down, deep-power-down (DPD) or self-refresh (SR) mode. This is achieved using the manual control register `SDRC.SDR_CMANUAL_p[3:0]` CMDCODE field which is defined on a per chip select basis. Entry and exit of these low-power modes is achieved using the relevant CMDCODE.

Once the memory associated with a CS has been powered down in deep-power-down mode it cannot be powered up by dynamic power management features. It can only exit the low-power state through the programming of the relevant CMDCODE. The SDRC can automatically exit other low-power modes.

#### 11.2.5.4.3.2 Clock-Controlled Memory Power Management

The SDRC power-management register (`SDRC.SDR_POWER_REG`) contains the EXTCLKDIS field, which controls suspension of the external clock on a per-CS basis. Writing 1 to this field in the relevant register freezes the clock with a latency dependent on the `SDRC.SDR_POWER_REG` register programming. Subsequently, writing 0 to this field in the relevant register enables the clock with a latency dependent on the `SDRC.SDR_POWER_REG` register programming.

#### 11.2.5.4.3.3 Manual Power-Down Mode Power Management

For automatic power-down mode refer to [Section 11.2.4.4.9.2](#). The programming model for manual power-down mode is different for an SDR and a DDR.

##### SDR Mechanism/Power-Down Mode Entry

1. Ensure that no accesses are pending or active.
2. Program the CMDCODE field of the relevant manual command register to 0001.  
This ensures that all banks are idle by executing a precharge all command.
3. Wait two clock cycles.
4. Program the CMDCODE field of the relevant manual command register to 0000.  
This executes a NOP command.
5. Program the CMDCODE field of the relevant manual command register to 1000.  
This sets CKE low.
6. Maintain the clock at a stable value.

##### SDR Mechanism/Power-Down Mode Exit

1. Provide clock.
2. Program the CMDCODE field of the relevant manual command register to 0111.  
This sets the relevant CKE high.
3. Program the CMDCODE field of the relevant manual command register to 0000.  
This executes a NOP command.
4. Program the CMDCODE field of the relevant manual command register to 0001.  
This ensures that all banks are idle by executing a precharge.

The length of time the SDRC spends in power-down mode must not exceed the refresh period; otherwise, data becomes corrupted.

For a DDR, the sequence is as follows:

##### DDR Mechanism/Power-Down Mode Entry

1. Ensure that no access is currently pending or active.
2. To reduce power consumption (not mandatory): disable DLL by setting the ENADLL field of the

relevant SDR.C.SDR\_C\_DLLA\_CTRL register to 0x0.

3. Program the CMDCODE field of the relevant manual command register to 0001. This ensures that all banks are idle by executing a precharge all command.
4. Program the CMDCODE field of the relevant manual command register to 0000. This executes a NOP command.
5. Program the CMDCODE field of the relevant manual command register to 1000. This sets the relevant CKE low.
6. Maintain the clock at a stable value.

#### **DDR Mechanism/Power-Down Mode Exit**

1. Provide clock.
2. Program the CMDCODE field of the relevant manual command register to 0111. This sets the relevant CKE high.
3. Program the CMDCODE field of the relevant manual command register to 0000. This executes a NOP command.
4. Program the CMDCODE field of the relevant manual command register to 0001. This ensures that all banks are idle by executing a precharge all command.
5. Enable DLL by setting the ENADLL field of the relevant SDR.C.SDR\_C\_DLLA\_CTRL register to 0x1.

The amount of time the SDRC spends in power-down mode must not exceed the refresh period; otherwise, data becomes corrupted.

#### **11.2.5.4.3.4 Deep-Power-Down Mode Power Management**

When in deep-power-down mode the power distribution to the entire memory array is cut. The programming model for deep-power-down mode is as follows:

##### **Deep-power-down Mode Entry**

- Precharge all banks (CMDCODE: 0x1). This ensures that all banks are idle.
- Enter deep-power-down mode (CMDCODE: 0x3).

##### **Deep-power-down Mode Exit**

- Exit deep-power-down mode (CMDCODE: 0x4).

The MR and EMR values are retained upon exiting deep-power-down mode.

---

**NOTE:** Because power-pown entry/exit sequences depend on memory devices, see the memory specification for the complete sequence.

---

#### **11.2.5.4.3.5 Manual Self-Refresh Mode Power Management**

The programming model for entering and exiting self-refresh mode is as follows:

##### **Self-Refresh Entry**

- Precharge all banks (CMDCODE: 0x1).
- NOP (CMDCODE: 0x0)
- Enter self-refresh mode (CMDCODE: 0x5).

There is no need for the software to disable the autorefresh in the SDR.C.SDR\_C\_RFR\_CTRL\_p register before entering self-refresh. The autorefresh counter is reset in hardware so that an autorefresh cycle is automatically generated immediately after a self-refresh exit, and before any other command.

##### **Self-Refresh Exit**

- Exit self-refresh mode (CMDCODE: 0x6).
- If needed, reconfigure SDRC registers as required.

- Enable autorefresh by programming:
  - The relevant SDRC.SDRC\_RFR\_CTRL\_p[23:8] ARCV field
  - The relevant SDRC.SDRC\_RFR\_CTRL\_p[1:0] ARE field to the desired refresh burst

### 11.2.5.5 Error Management

All data transfers in the SDRC operate a system of full handshaking. A valid read or write request that is presented to the SDRC by the L3 interconnect sequencer results in the SDRC acknowledging the transfer by raising the SCmdAccept flag. Failure to do this within a defined temporal window constitutes an error. Errors can arise from the following sources:

- Any transaction while the memory is in deep-power-down mode
- An illegal initiator access. The address of the last illegal access is captured in the SDRC.SDRC\_ERR\_ADDR register

If an error occurs, the software error handler performs the following actions:

- Interrogates the ERRORVALID field of the SDRC.SDRC\_ERR\_TYPE register to verify the presence of an error
- Interrogates the ERRORDPD field of the SDRC.SDRC\_ERR\_TYPE register to determine whether a transaction error resulting from the device being in deep-power-down mode is present
- Interrogates the ERRORCONNID field of the SDRC.SDRC\_ERR\_TYPE register to determine whether a transaction error resulting from an illegal access by an interconnect initiator is present
- Interrogates the ERRORADD field of the SDRC.SDRC\_ERR\_TYPE register to determine whether a transaction error resulting from an illegal address is present:
  - Interconnect access to an address outside the memory space (0x0)
  - Interconnect access to an address outside the register space (0x1)
- Writes 0 to the ERRORVALID field of the SDRC.SDRC\_ERR\_TYPE register to clear the active error status
- Executes error recovery from software

## 11.2.6 SDRC Use Cases and Tips

### 11.2.6.1 How to Program the VRFB

#### 11.2.6.1.1 VRFB Rotation Mechanism

An inherent limitation of SDRAM technology is high-memory latency caused by page-miss penalties incurred when downloading to a memory cache. For example, switching from one page to another in external memory can cause a page-miss, indicating that the page accessed for the current pixel is different from that for the previous pixel.

A DMA engine is used to rotate pictures in external DRAM, but this rotation method increases the number of page misses.

The efficient way to rotate image data in external SDRAM is to use the VRFB module, which is an RE embedded in the SMS of the OMAP device, as shown in [Figure 11-62](#). It is configured in the SMS registers.

**Figure 11-62. SDRC Subsystem Overview**

sdr-019

Accessing images stored in external SDRAM in a non-natural order requires an address transaction: the virtual address of an image is translated into a physical address in the corresponding buffer. Address translation causes an image to be rotated in 0-, 90-, 180-, or 270-degree views. With multiple views of the image, the RE can change addresses and issue multiple requests to the SDRC so that a maximum of consecutive accesses is performed, thus decreasing the number of page-miss penalties. The RE cannot reorder requests to the SDRAM.

A VRFB context defines the configuration used to access a picture in external SDRAM. For each VRFB context, a set of registers in the SMS describes:

- The size of the page (height and width)
- The picture parameters before rotation (width, height, and pixel format)
- The rotation angle (0-, 90-, 180-, or 270-degree)
- The physical base address in external memory

Any initiator in the OMAP device can access up to 12 images simultaneously, each image having an independent context. These 12 contexts is considered virtually addressed image buffers. Each context is assigned to a physical image buffer.

The virtual address space of each context is subdivided into four separate address regions pointing to the same physical image buffer but corresponding to the four possible rotations: 0/90/180/270.

After the VRFB context is configured, all data accesses to an address space are automatically translated when accessing SDRAM through the RE.

### 11.2.6.1.2 Setting a VRFB Context

**NOTE: YUV Format**

The YUV standard shows a color space with three elements:

- Y for luminance
- U for chrominance
- V for chrominance

As shown in [Figure 11-63](#), pixel format (not pixel size) used in the YUV standard is spread onto a 32-bit data structure:

- This 32-bit data structure represents a packet of two pixels: P0 and P1.
- Each element (Y0, Y1, U, and V) is coded in 8 bits.
- P0 = Y0; U, V, and P1 = Y1, U, V.

There are 24 bits of information per pixel (Y, U, and V); however, because the chrominance elements U and V are common to both P0 and P1 pixels, only 16 bits are used to store a pixel in YUV format. The YUV standard uses a 32-bit data structure to represent 2 pixels; the pixel format uses 32 bits (4 bytes).

Thus, when defining YUV image parameters, the image width must be set to one-half the number of pixels per row and the pixel format must be set to 4 bytes, because the YUV pixel data is spread onto a 32-bit word representing 2 pixels.

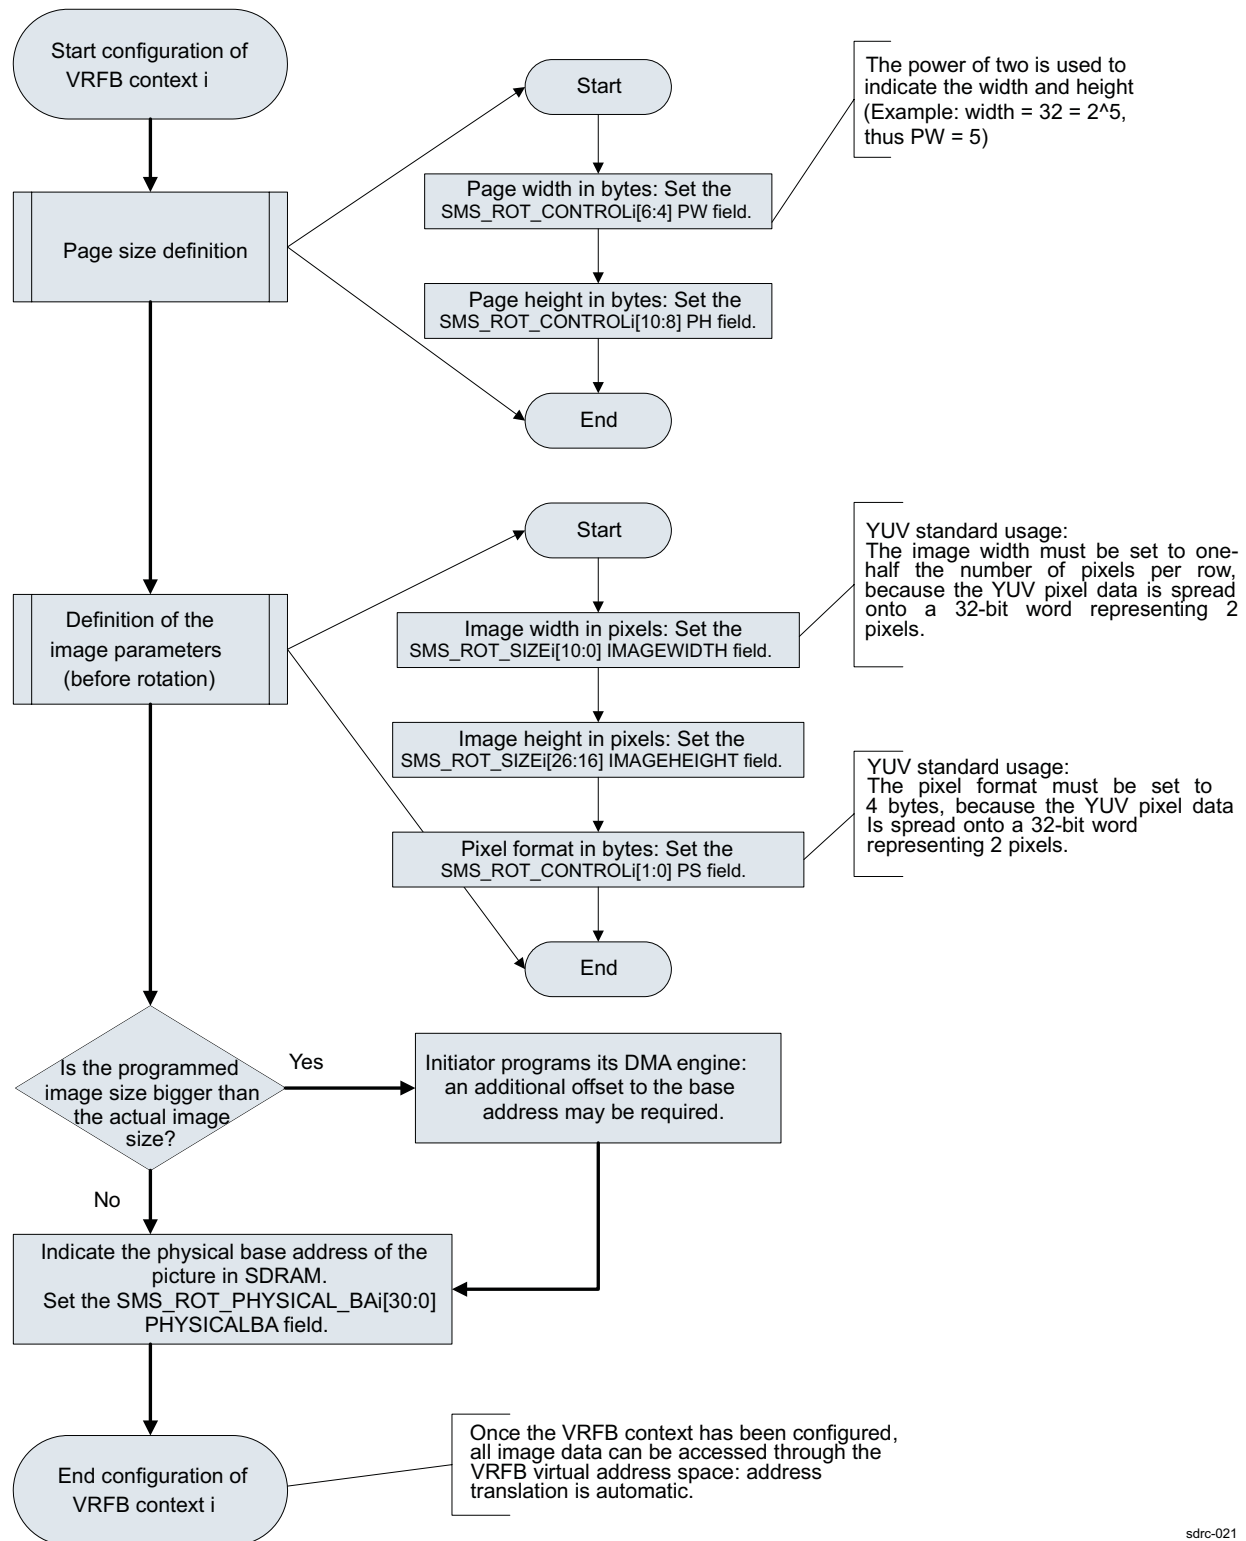

[Figure 11-63](#) shows the pixel representation of the YUV format.

**Figure 11-63. YUV Format: Pixel Representation**

[Figure 11-64](#) shows a generic way to configure a VRFB context to perform a rotation view on pixel data in external DRAM.

Figure 11-64. VRFB Context Configuration

sdrc-021

Figure 11-65 is an example of VRFB context configuration using both RGB and YUV image formats. This example represents the configuration of a 1024-byte page size (32 x32 byte page) and a 240 x240 image size using VRFB context 1.

Figure 11-65. Example of VRFB Context 1 Configuration

Table 11-107 lists guidelines for calculating image size.

sdrc-022

**Table 11-107. Calculating Image Size<sup>(1) (2)</sup>**

Steps		RGB16 Format (16-Bit Pixel Format)		YUV Format (32-Bit Pixel Format)	
		IMAGEWIDTH	IMAGEHEIGHT	IMAGEWIDTH	IMAGEHEIGHT
1	Calculate the required number of pages per line and per column.	240 pixels/32 bytes x2 bytes per pixel = 15 pages per line	240/32 rows = 7.5, rounded to 8 pages per column	120 pixels/32 bytes x4 bytes per pixel format = 15	240/32 rows = 7.5, rounded to 8
2	Using the number of pages calculated in Step 1, calculate the image size in pixels.	15 x32 bytes/2 bytes per pixel = 240	8 x32 rows = 256	15 x32 bytes/4 bytes per pixel format = 120	256

<sup>(1)</sup> Working on a page basis, the image size must be a multiple of the page size.

<sup>(2)</sup> Depending on the page dimensions and the image size, the programmed image size (256) is larger than the actual image size (240).

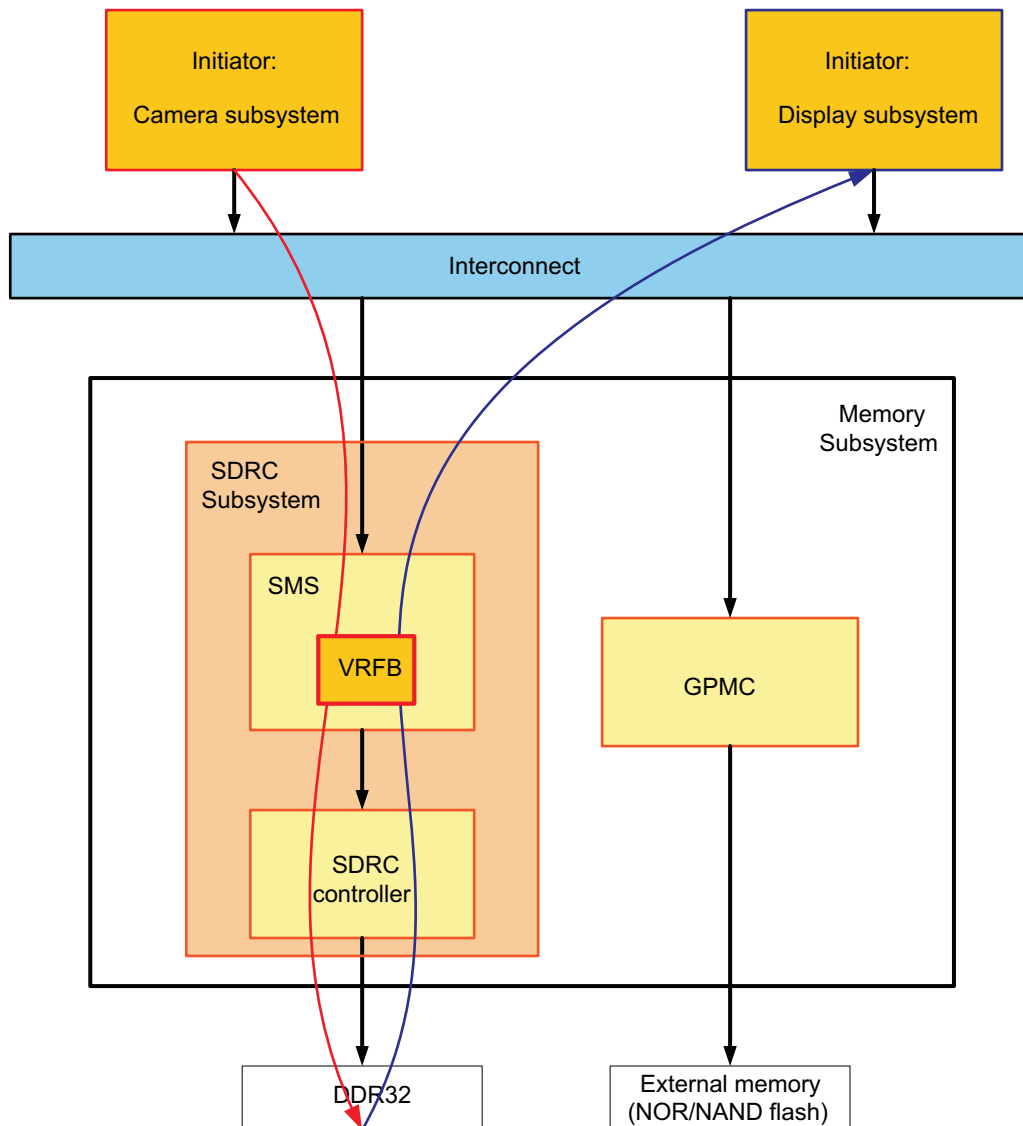

To use VRFB rotation, each initiator must configure its DMA engine correctly; an additional offset to the base address may be required. For details, see [Chapter 15, Display Subsystem](#).

### 11.2.6.1.3 *Applicative Use Case and Tips*

#### **Use Case Scenario: Display a Rotated QVGA Image**

[Figure 11-66](#) shows the use case for displaying a rotated QVGA image. The camera captures an image with a particular rotation and stores the pixel data in external memory. Displaying the image on the LCD requires a different orientation.

Figure 11-66. Display a Rotated QVGA Image

sdrc-023

The following components interact while displaying the rotated image:

- SDRC subsystem
- Camera subsystem
- Display subsystem
- External DDR
- VRFB

The following conditions exist for this application:

- QVGA image size is 320 x240 (width xheight).
- Pixel format is YUV4:2:2 (YUV2) in little endian.
- The rotation view is 90 degrees.
- The VRFB context is VRFB context 1.
- The camera module writes QVGA images to external DRAM at 15 fps.
- The display subsystem reads QVGA images from external DDR32 at 60 fps and displays them on the LCD screen.

- Read and write initiators use burst mode:
  - The camera uses 8 × 64-bit burst size.
  - The display uses 8 × 32-bit burst size.
  - Double-indexing mode is selected.
- The physical address of the buffer in external memory is 0x8030 0000.
- The memory allocation for the buffer is 320 × 240- × 16-bit (or 160 × 240 × 32-bit).
- The camera subsystem uses its dedicated DMA channel 0.
- The display subsystem uses its video channel 1.

### **Configuring the VRFB Through the SMS Registers**

The size of the page supported by the DDR32 memory is 1K byte, which is arranged as 32 × 32 bytes page (width × height).

Configuring the page size:

- **SMS\_ROT\_CONTROL<sub>n</sub>[6:4]** PW = 5 (where n = 1)
- **SMS\_ROT\_CONTROL<sub>n</sub>[10:8]** PH = 5

Configuring the image parameters:

- **SMS\_ROT\_SIZE<sub>n</sub>[10:0]** IMAGEWIDTH = 160 (where n = 1)
- **SMS\_ROT\_SIZE<sub>n</sub>[26:16]** IMAGEHEIGHT = 256
- **SMS\_ROT\_CONTROL<sub>n</sub>[1:0]** PS = 2

Physical base address and rotation angle:

- **SMS\_ROT\_PHYSICAL\_BA<sub>n</sub>[30:0]** PHYSICALBA = 0x8030 0000 (where n = 1).

The image data is accessed at the following virtual address range for 90-degree rotation: 0x7500 0000 - 0x75FF FFFF.

#### **CAUTION**

Image rotation using the YUV2 image format causes the stream to become untidy. The display must be specifically configured to read and reorganize the stream to conform to the YUV2 standard.

### **Tips for Configuring Successful Rotation**

The following guidelines ensure optimal image rotation:

- Page arrangement:
 

Usually, the recommendation is to have a *square* page. If this is not possible, the longest page side should correspond to the access direction that requires the maximum bandwidth; set the longest page side to optimize the page break.

Using a 1024-byte page size, a 32 × 32-byte page arrangement is used as an example. With a 2K-byte page organized as a 32 × 64 byte page, depending on the read or write operation, set the longest page size to optimize the page break. If 0 is written and the 270-degree view is read, page height is greater than page width (PH > PW). Set PH to 64 bytes (PH = 6).
- Virtual address memory arrangement:
 

When accessing image data through virtual addresses, the maximum line size supported by the VRFB is 2,048 pixels.

In the memory buffer, the distance between two vertically adjacent pixels is fixed at 2,048 multiplied by the pixel format in bytes. This means that when reading or writing image data through virtual addresses, there must be an offset of: (2048 - IMAGEWIDTH) × PS bytes at the end of every line.
- Base address alignment:
 

For optimization, the base address is aligned on the page size. For instance, a 1K-byte page size organized as a 32 × 32-byte page is aligned on 0x400 (to be adjusted on the base address).

- To improve performance on 90° rotation consider two things:
  - Because a read access can appear more critical than a write access, a posted write may be appropriate.
  - When performing burst accesses with 90° or 270° rotation views, the burst is split on the memory side, adding latency.
    - For a burst access with 90° rotation, split the data of the burst on the write side (not the read side):
      - Write in 270° and read in 0°.

## 11.2.6.2 SMS Mode of Operation

### 11.2.6.2.1 SDRAM Memory Scheduler and Arbitration Policy

The SDRAM memory scheduler improves access to external memory by:

- Optimizing SDRAM bandwidth
- Prioritizing requests to external memory

This mechanism relies on a complex arbitration policy that employs specific terminology:

- Group: a FIFO queue of requests from initiators
- Class: A collection of groups
- Transaction: A full burst request
- Arbitration grant: Authorization of a service requested by an initiator

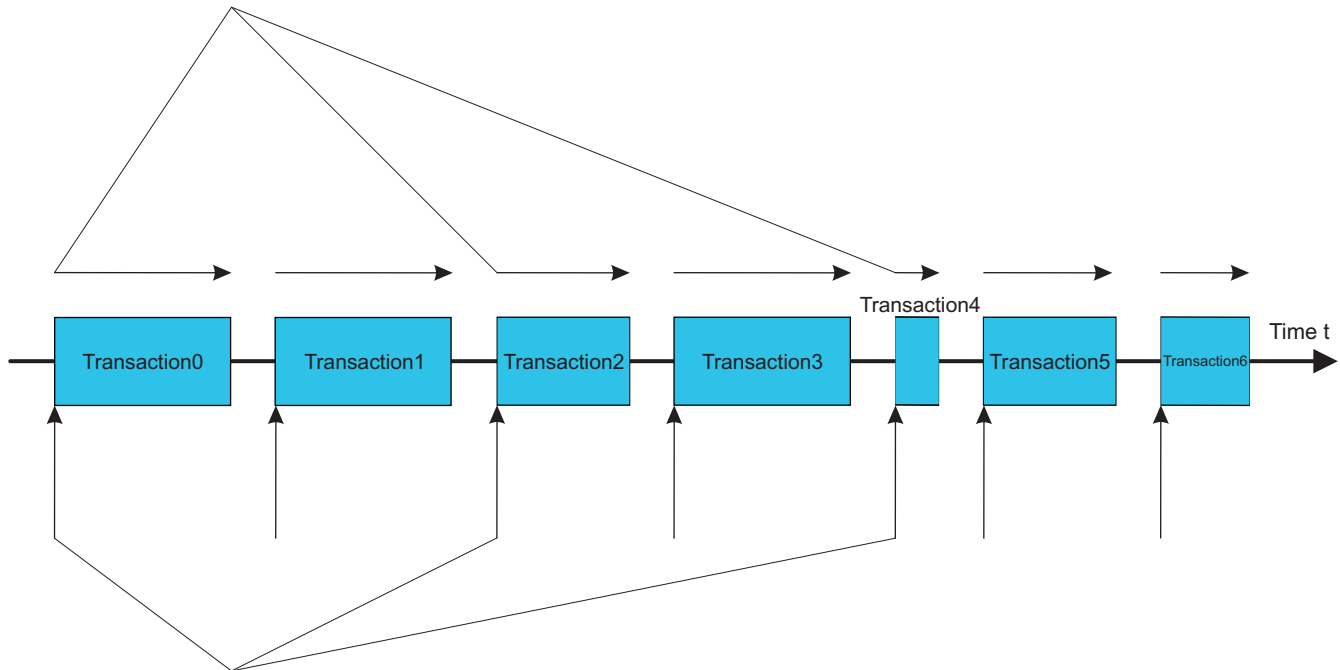

The arbitration policy operates on two interdependent mechanisms:

- The arbitration decision, which establishes priority for processing requests. The question: Which request is processed next? occurs on a transaction boundary.
- Arbitration granularity, which determines the length of an arbitration grant. The question: How long to keep the grant? defines the boundary of the arbitration decision point in time.

[Figure 11-67](#) shows the link between these two concepts. On a transaction boundary, the questions: What request is serviced next, and for how long? merge the two mechanisms. The mechanisms for specifying the granularity of requests also influence the boundary of a transaction.

**Figure 11-67. Arbitration Granularity Versus Arbitration Decision**

Duration of a transaction:  
How long to track the transaction?  
(it depends on the granularity settings)

Arbitration decision on a transaction boundary:  
Which group has the priority?

sdr-024

### 11.2.6.2.2 Arbitration Decision

The SMS module controls arbitration. Requests from initiators for access to the external SDRAM are collected into several independent FIFO queues, and each queue is assigned to a class. Priority is then assigned to groups and classes; this defines the next request to be serviced.

#### 11.2.6.2.2.1 Burst-Complete Mechanism

The burst-complete mechanism applies granularity to the arbitration scheme. Access cannot be granted to a group within a class until a complete burst has been stored in the FIFO.

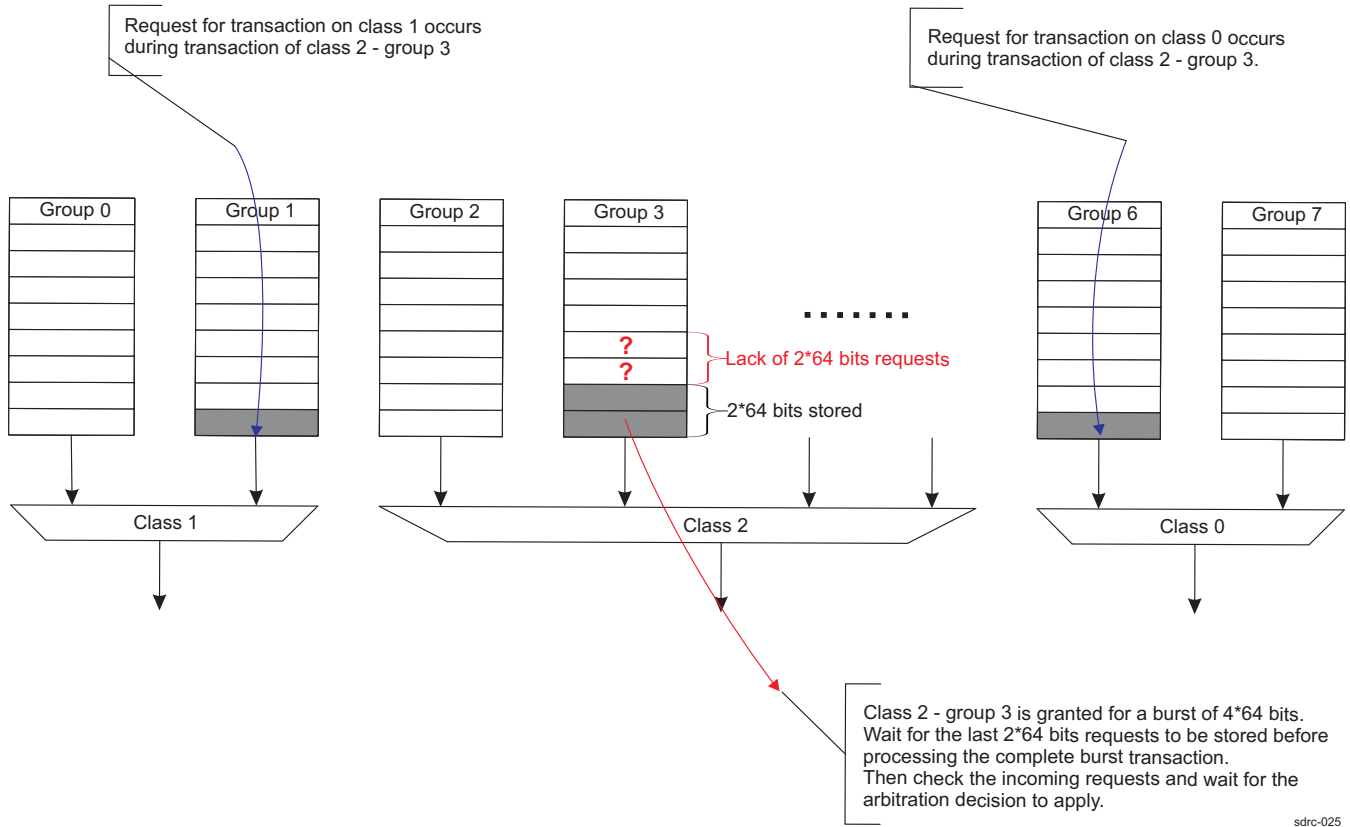

Example:

There is no ongoing transaction on Class 0. The initiator requests a 4 x64-bit burst on Group 3 of Class 2 ([SMS\\_CLASS\\_ARBITER2](#)[27] BURST-COMPLETE = 0x1). Only 2 x64-bit requests are stored in the FIFO.

The mode of operation is:

- Wait for the last 2 x64-bit request to be stored in the FIFO.
- Arbitration is requested once all requests of a burst have been received.
- After the 4 x64-bit burst is complete, the transaction occurs.
- The arbitration choice mechanism resumes:
  - Were there any incoming requests during the last transaction?
  - What is the next request to be serviced/granted?

**Figure 11-68. BURST-COMPLETE On Class 2-Group 3**

### 11.2.6.2.2.2 Priority Between Groups

The SMS.SMS\_CLASS\_ARBITERi[7:6] HIGHPRIOVECTOR field defines the priority between groups in a class.

### 11.2.6.2.2.3 Priority Between Classes

Class 0 always has the highest priority. Then, a weight is programmed within the arbitration of Class 1 and Class 2:

- The SMS.SMS\_INTERCLASS\_ARBITER[23:16] CLASS1PRIO field specifies the number (M) of transactions dedicated to Class 1.
- The SMS.SMS\_INTERCLASS\_ARBITER[7:0] CLASS2PRIO field specifies the number (N) of transactions dedicated to Class 2.

M and N parameters are used to set a PWM arbitration. For instance, two schemes appear: at time t, Class 1 is serviced for M cycles, and is directly followed by service to Class 2 for N cycles. If Class 2 is serviced first for N cycles, then Class 1 is granted for M cycles. Arbitration is given more importance; Class 1/2 is favored over Class 2/1. As shown in [Figure 11-69](#), two arbitration schemes can appear:

- Class 0 is serviced first, followed by Class 1, and then Class 2 (C0 - C1 - C2).
- Class 0 is serviced first, followed by Class 2, and then Class 1 (C0 - C2 - C1).

**Figure 11-69. Priority Between Classes**

SMS\_INTERCLASS\_ARBITER[7:0] CLASS1PRIO field:  
defines the number M of transactions dedicated to class 1.

SMS\_INTERCLASS\_ARBITER[23:16] CLASS2PRIO field:  
defines the number N of transactions dedicated to class 2.

sdrc-026

### 11.2.6.2.3 Arbitration Granularity

Arbitration is the mechanism that give more or less importance to incoming requests depending on the initiator origin. Granularity influences the boundary of a transaction because it imposes the following questions:

- How many requests to service?
- How long to track the current transaction?
- When to make the next arbitration decision, or when does the next transaction boundary occur?

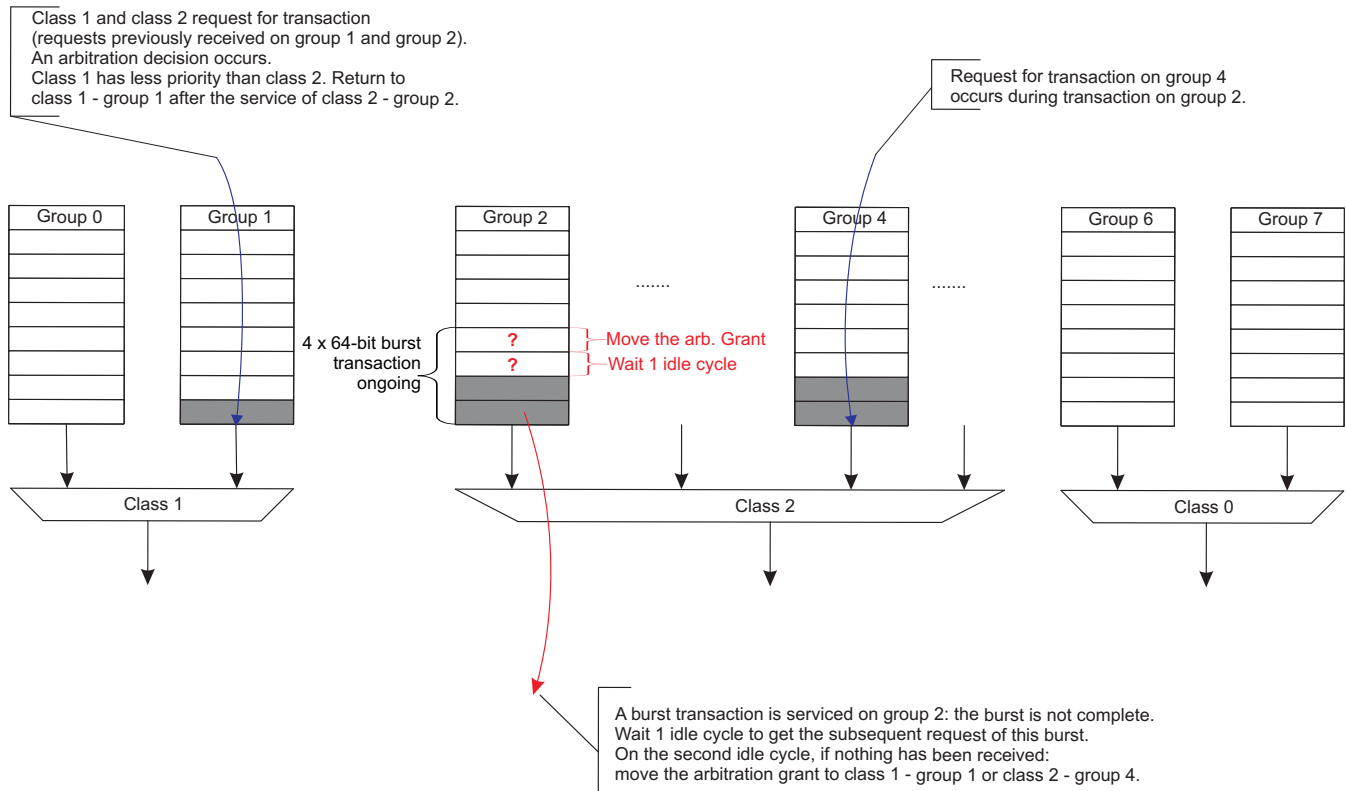

#### 11.2.6.2.3.1 Idle Cycle

The idle gives more granularity to the arbitration; it lets the arbiter wait one idle cycle before moving the arbitration grant to another thread.

Within a burst (see [Figure 11-70](#) for an example):

1. A thread requests a burst transaction. According to the thread ID, the last request was serviced on Class 2 - Group 2.
2. The thread cannot provide the subsequent request of the burst. The module waits for one idle cycle without moving the arbitration grant, to receive the subsequent request (from the same thread).
3. On the second idle cycle, if the subsequent request has not been received, the arbitration grant is moved so that a request from another thread is serviced.

**Figure 11-70. Idle Cycle Mechanism Within A Burst**

Two bursts must be serviced at the burst boundary. One idle cycle after servicing these two bursts, the arbitration grant is moved.

### 11.2.6.2.3.2 Extended-Grant Mechanism

The extended-grant mechanism gives additional granularity to the arbitration. An extended grant defines the number of consecutive transactions (from 1 to 3) a group is granted.

Example:

Requests were already available on Class 1-Group 0 and Class 2-Group 3.

An arbitration decision occurs: grant access to Class 1-Group 0.

A request is now being serviced on Class 1-Group 0 with `SMS_CLASS_ARBITER1[9:8]`

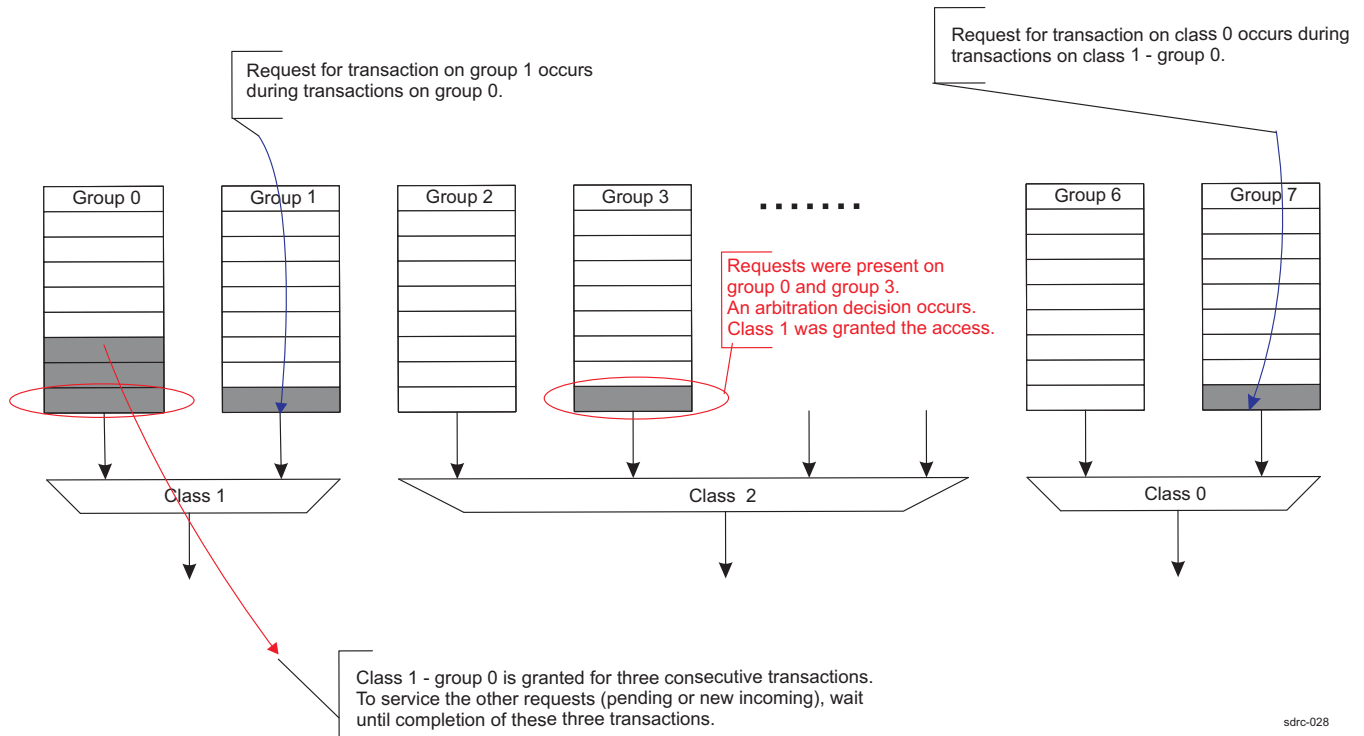

`EXTENDEDGRANT = 0x3` (three consecutive transactions are granted to Group 0). The mode of operation is:

- Process the request for three cycles.
- If another request comes from another class (even Class 0) during the processing, it is ignored; the arbiter does not treat incoming requests.
- After three consecutive transactions, return to the arbitration decision:
  - Were there any incoming requests during the last transaction?
  - What is the next request to be serviced?

Figure 11-71 shows this mechanism on Class 1-Group 0:

**Figure 11-71. Example of EXTENDEDGRANT Mechanism**

sdr-028

**11.2.6.2.3.3 Number of Service Mechanism.**

The `SMS_CLASS_ROTATIONm[4:0]` NOFSERVICES field defines the number of consecutive transactions (from 1 to 31) the VRFB is granted. For more information on LRU policy and Number of Service, refer to [Section 11.2.4.1.3](#).

**11.2.6.2.4 How these Mechanisms Interact**

As described in the previous sections, the arbitration within the SMS module is based on several mechanisms giving even more importance to the arbitration. When we need to grant the access on a transaction boundary, we recall that the question we have to answer is: What will be the next request to be serviced, and for how long?

Thus, the two important concepts regarding the SMS mode of operation are:

- The arbitration decision: we choose the next request to be serviced and so we grant it the access to the external memory.
- The arbitration granularity: depending on the mechanism used, we define the boundary of the transaction: how long do we keep the grant?

Figure 11-72 describes the decision happening between classes.

Figure 11-73 explains the priority between groups within Class 1.

So far, the arbitration decision has taken place at class boundaries and within a class containing two groups. Figure 11-74 recalls the generic way to service and therefore prioritize the requests within a class. Finally, Figure 11-75 recalls mechanisms used to define the boundary of the transaction being serviced (how long do we keep the grant?).

### 11.2.6.3 Typical SDRC connection to an External SDRAM Device

The SDRAM controller (SDRC) transfers data to and from standard SDRAM based on user request. It interfaces between an external SDRAM memory subsystem and the SDRAM Memory Scheduler that optimizes memory access for each application.

This section shows a typical connection between the SDRC module and an external SDRAM. The use case explains important parameters and their required configurations.

#### **11.2.6.3.1 External Memory Attached to the SDRC Module**

The SDRC module supports the following external memory types:

- Mobile single data rate (SDR)-SDRAM devices
- Low-power DDR SDRAM device

This section describes how to calculate the SDRC timing parameters and provides a typical setup of those parameters according to the access performed.

A 512 Mb mobile DDR SDRAM memory with the following characteristics has been chosen:

- Type: Mobile DDR SDRAM
- Size: 512 Mbits (8M x16 x4 banks)
- Data bus: 16-bit width
- Speed: 133-MHz clock frequency, 7.5-ns clock period

#### **11.2.6.3.2 DDR-SDRAM Memory General Facts**

This section details the interconnection of the mobile DDR SDRAM with the SDRC interface; it then gives a basic SDRAM workflow and introduces the difference between the autorefresh and self-refresh concepts.

##### **11.2.6.3.2.1 Mobile DDR Interconnection With SDRC**

[Figure 11-76](#) shows a simplified interconnection diagram of the mobile DDR SDRAM with the SDRC interface.

**Figure 11-76. Mobile DDR SDRAM to SDRC Interface**

Table 11-108 lists the I/Os of the SDRC module from an SDRC point of view.

**Table 11-108. SDRC Signals Description**

Signal Name	I/O <sup>(1)</sup>	Description
sdr_c_clk, sdr_c_nclk	O	Address and control input signal sample clock
sdr_c_cke0	O	Clock-enable signal
sdr_c_ncas, sdr_c_nras, sdr_c_nwe	O	Column address strobe, row address strobe, and write enable. Defines the command being entered
sdr_c_ba0, sdr_c_ba1	O	Bank address outputs
sdr_c_dm[3:0]	O	Data mask. sdr_c_dm[0] corresponds to the data on sdr_c_d[7:0]; sdr_c_dm[1] corresponds to the data on sdr_c_d[15:8]. sdr_c_dm[3:2] unconnected.
sdr_c_ncs0	O	Chip-select for external SDRAM selection (only one enabled here)
sdr_c_a[12:0]	O	Address bus sdr_c_a[14:13] unconnected.
sdr_c_d[15:0]	I/O	Data bus sdr_c_d[31:16] unconnected.
sdr_c_dqs0, sdr_c_dqs1	I/O	DDR data strobe. Output with read data, input with write data sdr_c_dqs[3:2] unconnected.

<sup>(1)</sup> I = Input; O = Output

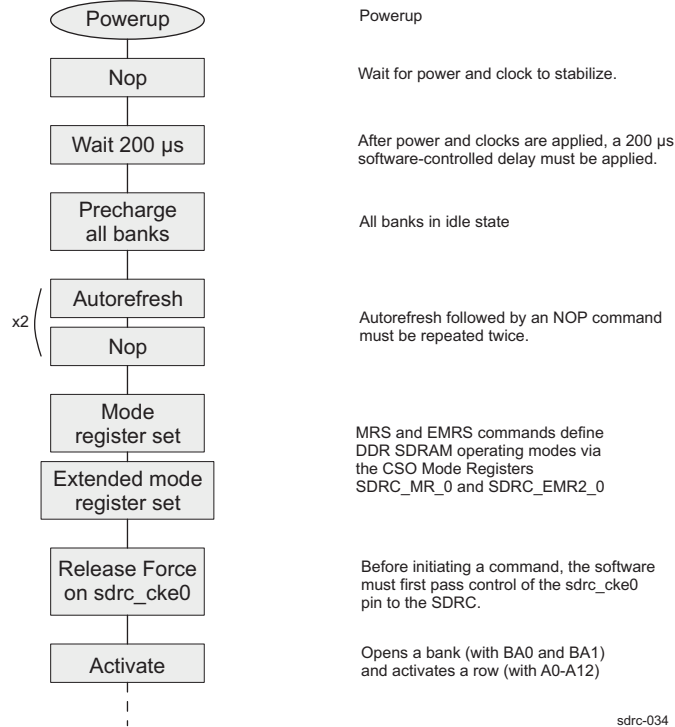

### 11.2.6.3.2.2 SDRAM Operating Flow

This section describes the basic DDR-SDRAM workflow. For more information about the SDRAM operation, see the *Low Power Double Data Rate (LPDDR) SDRAM* specification (JEDEC committee JC42.3) or other appropriate mobile DDR SDRAM documentation.

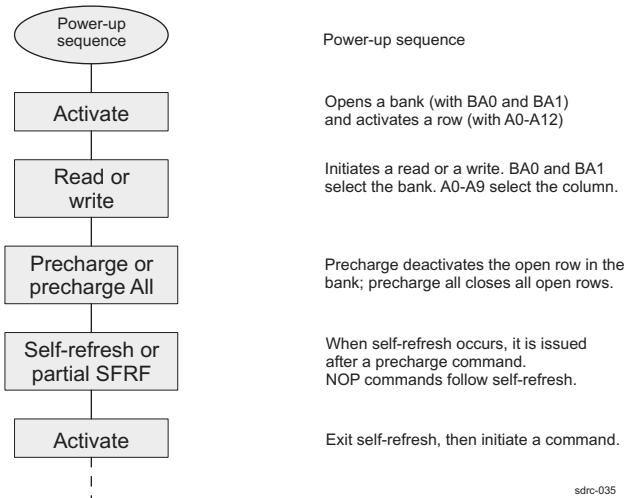

Figure 11-77 shows a simplified operating diagram of the power-up sequence required to correctly power up an SDRAM.

Figure 11-78 shows a simplified diagram of the normal operating sequence.

**Figure 11-77. SDRAM Power-Up Sequence**

**Figure 11-78. Normal Operating Sequence**

### 11.2.6.3.2.3 Autorefresh vs Self-Refresh

What are the differences between an autorefresh and a self-refresh?

DDR SDRAM devices require a refresh of all rows in 64-ms interval as specified in the JEDEC LPDDR SDRAM standard. The autorefresh period may depend on the technology. Each refresh is generated either by an autorefresh command from the SDRC in normal mode, or by an internal counter in the SDRAM in self-refresh mode.

The autorefresh command must be generated each time a refresh is required. The average refresh interval period (tREFI), also called autorefresh duty cycle, is given by the division of 64 ms into the number of rows (8192 for the selected mobile DDR SDRAM). An internal refresh controller in the SDRAM takes care of the refreshing process and control, and the autorefresh command must be issued regularly by the SDRAM controller.

The self-refresh command is used when the system is powered down and enables data retention even if the clock is stopped.

For more information on refresh modes, see [Section 11.2.4.4.7, Refresh Management](#).

### 11.2.6.3.3 SDRC Typical Setup

When a given external memory device is selected, the SDRC must be configured according to the memory parameters.

#### 11.2.6.3.3.1 Memory Type General Configuration

[Table 11-109](#) summarizes the mobile DDR SDRAM address configuration.

**Table 11-109. Mobile DDR SDRAM Address Configuration**

Item	Description
RAM size	512 Mbits
Number of banks	4
Bank address pins	BA0, BA1
Row addresses	A0–A12
Column addresses	A0–A9
tREFI (μs)	7.8

The following parameters must be configured in register `SDRC.SDRC_MCFG_p`, where  $p = 0$  (configuration register for the SDRAM connected to the `sdrc_ncs0`) as follow:

- `SDRC_MCFG_p[19]` ADDRMUXLEGACY = 0x1 selects the flexible address mux scheme.
- `SDRC_MCFG_p[1:0]` RAMTYPE = 0x1 selects DDR-SDRAM rather than SDR-SDRAM.
- `SDRC_MCFG_p[2]` DDRTYPE = 0x0 is the default setting that sets the DDR memory type as mobile DDR.
- `SDRC_MCFG_p[17:8]` RAMSIZE = 0x020 is the RAM address space size expressed in 2M-byte chunks. In this example, the DDR SDRAM size is 512M-bits or 64M-bytes. These are 32 2M-byte chunks, that is, 20 2M-byte chunks expressed in hexadecimal format.
- `SDRC_MCFG_p[4]` B32NOT16 = 0x0. The external SDRAM bus width is 16-bit.
- `SDRC_MCFG_p[26:24]` RASWIDTH = 0x2 because RAS width is 13 bits.
- `SDRC_MCFG_p[22:20]` CASWIDTH = 0x5 because CAS width is 10 bits.
- `SDRC_MCFG_p[3]` DEEPPD = 0x1. The memory device supports deep-power-down mode.
- Other bit fields as LOCKSTATUS and BANKALLOCATION may be set up as required.

#### 11.2.6.3.3.2 Mode Register Configuration

The SDRAM mode of operation is defined through the mode register as follows ( $p = 0$  for CS0):

- `SDRC_MR_p[6:4]` CASL = 0x3. The CAS latency, or read period, is 3 clock cycles long.
- `SDRC_MR_p[2:0]` BL = 0x2. The memory burst length must be set at 4 for DDR SDRAM.
- `SDRC_MR_p[3]` SIL = 0x0. The serial mode is always used.
- `SDRC_MR_p[9]` WBST = 0x0. Write burst equals read burst.

To configure the DLL/CDL module as second clock write path, set up the `SDRC_DLLA_CTRL` register as follows:

- [SDRC\\_DLLA\\_CTRL](#)[7] WRITEDDRCLKX2DIS = 0x1 so that the DLL/CDL write path can be used as mobile DDR write path.
- [SDRC\\_DLLA\\_CTRL](#)[3] ENADLL = 0x1 enables the DLL.
- [SDRC\\_DLLA\\_CTRL](#)[2] LOCKDLL must be set to 0 for high-speed operations.
- [SDRC\\_DLLA\\_CTRL](#)[1] DLLPHASE = 0x0 for read accesses and 0x1 for write accesses. This corresponds to a CDL delay of a quarter of a clock period or a fifth of a clock period, respectively.

The recommended configuration is to use the data path using double frequency logic rather than the DLL/CDL write path. This is obtained by setting WRITEDDRCLKX2DIS to 0x0.

### 11.2.6.3.3.3 SDRAM Programmable AC Timing Parameters Configuration

Some parameters are hard-coded in the SDRC. Apart from those parameters, users can program a list of programmable AC timings using the [SDRC\\_ACTIM\\_CTRLA\\_p](#) and [SDRC\\_ACTIM\\_CTRLB\\_p](#) registers, where p = 0 or 1, depending on the SDRAM chip (in the section p = 0, because only one chip is connected to the SDRC interface). The setup values are expressed in clock cycles.

[Table 11-110](#) summarizes the most important AC timing parameters to be configured. F = 133 MHz and tCK = 7.5 ns for the clock signal.

**Table 11-110. Mobile DDR SDRAM AC Timings Parameters**

AC Timing Parameter	Description	Duration (ns)
tRC	Row cycle time	67.5 (or 9 tCK)
tRAS	Row active time	45 (or 6 tCK)
tRP	Row precharge time	22.5 (or 3 tCK)
tRCD	nRAS to nCAS delay time	22.5 (or 3 tCK)
tRFC	Autorefresh cycle time	80 (min)
tRRD	Row active to row active delay time	15 (or 2 tCK)
tDPL	Data-in to precharge command time or tWR (write recovery time)	15 (or 2 tCK)
tWTR	Write-to-read time (also called tCDLR). Last data in to read command	1 tCK
tCKE	CKE minimum pulse width time (high and low pulse width)	2 tCK
tDAL	Last data in to active delay time	2 tCK + tRP
tXSR	Exit self-refresh to active command time	120
tXP	Exit power-down to active command time	25

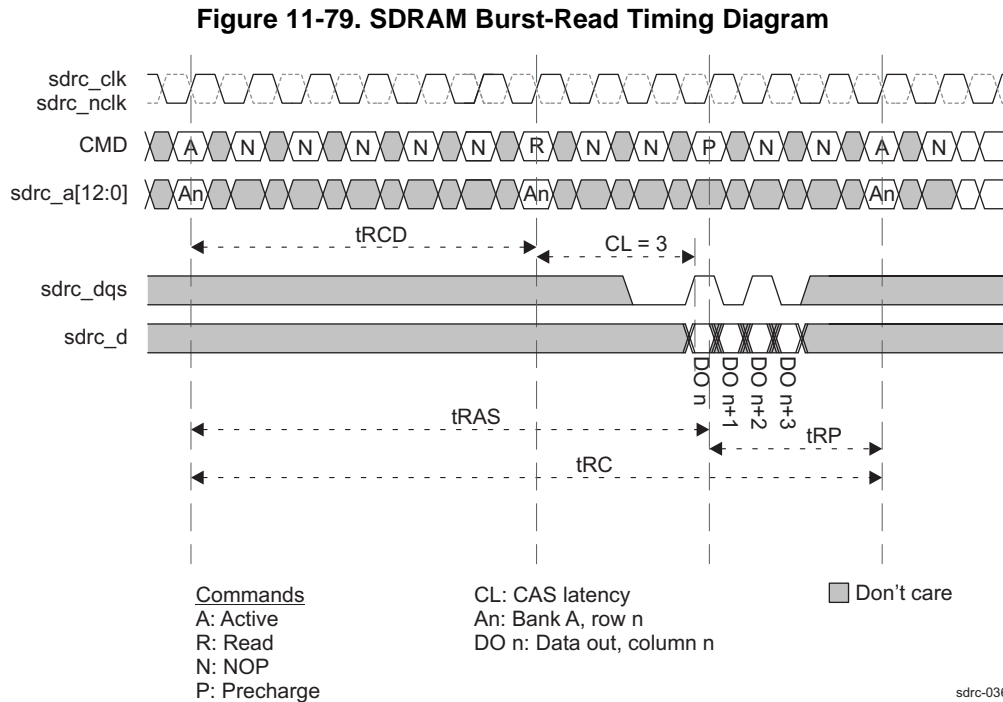

Before calculating the timing parameters on the SDRC side, let's define some terms used to describe the timing between the controller and the memory device:

- nRAS to nCAS delay time is the row-activating phase, or minimum time between an ACTIVE and a READ or WRITE command.
- CAS latency is the time between a READ or a WRITE command and the data driven on DQ lines. With CL = 3, the first data element is valid at (2 × tCK + tAC) after the clock at which the READ command is registered. With CL = 2, the first data element is valid at (tCK + tAC) after the clock at which the READ command is registered. tAC is the DQ output window relative to the clock, and is the long term component of DQ skew.
- Row active time is the minimum bank activate to PRECHARGE time. A PRECHARGE cannot start until tRAS has elapsed.
- Row precharge time: Following the PRECHARGE command, a subsequent command to the same bank cannot be issued until tRP is met. After tRP, an ACTIVE command to the same bank can be initiated.
- Row cycle time is the minimum time between the activation of a first row and the activation of another row in the same bank. It is also called ACTIVE to ACTIVE command period.
- Last data in to active delay time is the minimum time between the last data in and the next ACTIVE

command.

- Autorefresh cycle time: Refreshing starts with an AUTO REFRESH command and ends when tRFC is met.

Figure 11-79 shows a simplified timing diagram of a burst read of SDRAM.

The `SDRC_ACTIM_CTRLA_p` register ( $p = 0$ ) must be programmed with the AC timing parameters listed in Table 11-111. Values are expressed in number of tCK periods.

**Table 11-111. Calculation of the SDRC.SDRC\_ACTIM\_CTRLA\_p Timing Parameters**

DDR-SDRAM Parameter Name	Number of Clock Cycles (F = 133 MHz, tCK = 7.5 ns)	SDRC_ACTIM_CTRLA_p Bit Field Value
tRC	9	TRC = 0x09
tRAS	6	TRAS = 0x6
tRP	3	TRP = 0x3
tRCD	3	TRCD = 0x3
tRFC	80 / 7.5 (minimum)	TRFC = 0x0B
tRRD	2	TRRD = 0x2
tDPL	2	TDPL = 0x2
tDAL	2x1 + 4 (in clock cycles)	TDAL = 0x6

The `SDRC_ACTIM_CTRLB_p` register ( $p = 0$ ) must be programmed with the AC Timing Parameters listed in Table 11-112. Values are expressed in number of tCK.

**Table 11-112. Calculation of the SDRC.SDRC\_ACTIM\_CTRLB\_p (p = 0) Timing Parameters**

DDR-SDRAM Parameter Name	Number of Clock Cycles (F = 133 MHz, tCK = 7.5 ns)	SDRC_ACTIM_CTRLB_p Bit Field Value (p = 0)
tCDLR	1	TWTR [17:16] = 0x1
tCKE	2	TCKE [14:12] = 0x2
tXP	25 ns <sup>(1)</sup>	TXP [10:8] = 0x4
tXSR	120 / 7.5	TXSR [7:0] = 0x10

<sup>(1)</sup> JEDEC LPDDR SDRAM standard states 25 ns with a minimum of 1 clock period.

### 11.2.6.3.3.4 Autorefresh Management Configuration

In normal operation mode, the autorefresh is managed by the SDRAM refresh configuration register [SDRC\\_RFR\\_CTRL\\_p](#) (where p = 0). The autorefresh counter is uploaded with the result of (tREFI / tCK) - 50.

50 (cycles) is a margin in case a command is already in progress on the SDRAM interface, thus requiring delay before initiating the autorefresh command. See [Section 11.2.5.3.6, Autorefresh Management](#), for more details.

[Table 11-113](#) details the required configuration.

**Table 11-113. Calculation of the SDRC.SDRC\_RFR\_CTRL\_p (p = 0) Timing Parameter**

DDR-SDRAM Parameter Name	Contents Formula	<a href="#">SDRC_RFR_CTRL_p</a> Bit Field Value (p = 0)
Autorefresh counter value	$(7.8 \mu\text{s} / 7.5 \text{ ns}) - 50$	ARCV [23:8] = 0x03DE
Autorefresh enable	Load Autorefresh counter with 8 for maximum Autorefresh burst length	ARE [1:0] = 0x3

### 11.2.6.4 Camcorder Use Case: How to Configure the VRFB

#### 11.2.6.4.1 Overview

This section discusses the configuration of the VRFB for rotating the video on an external VGA FlatLink™ 3G. The VRFB receives a video from the camera subsystem as a sequence of images. These images are then saved into SDRAM through the SDRC. [Figure 11-80](#) is an overview of the VRFB in the camcorder use case.

**Figure 11-80. SDRC Camcorder Use Case Overview**

After the VRFB configuration, the rotation process is transparent to the MPU operations. Four buffers are required in SDRAM to ensure stabilization, a smooth encoding process, and a tearing-free preview on the LCD display. Each of the four buffers uses a concurrent context. For each context, the following parameters must be configured:

- Page and pixel size
- Picture parameter (image height and width)
- Buffer physical base address

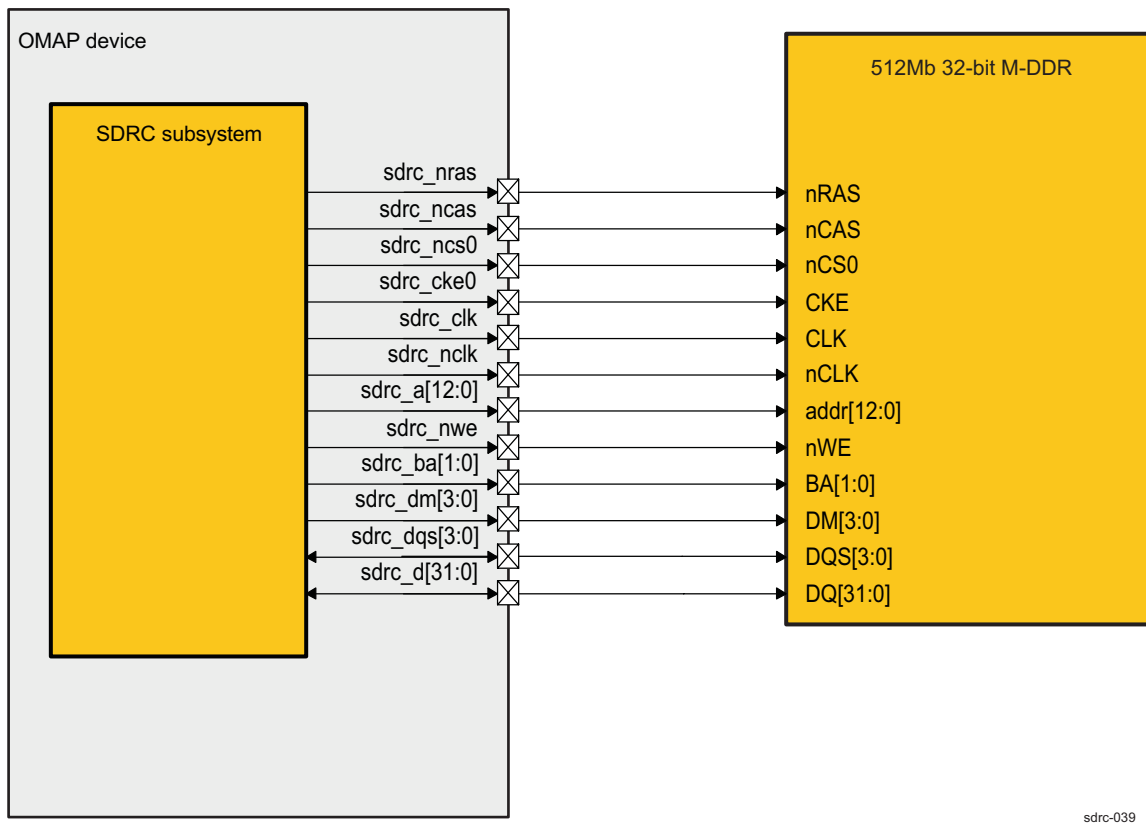

### 11.2.6.4.2 Environment

In this use case, the SDRC is connected to an external 512-Mb 32-bit Mobile-DDR SDRAM 166-MHz device (16M × 32).

The SDRC\_CLK clock source fed to the SDRAM is the PRCM CORE\_L3\_ICLK output.

The SDRAM device is connected to the SDRC subsystem (see [Figure 11-81](#)). For more information on the SDRC environment, see [Section 11.2.2, SDRC Subsystem Environment](#).

**Figure 11-81. SDRC Camcorder Use Case Environment**

### 11.2.6.4.3 Data Path

In this use case, the VRFB manages the rotation of the video stream, which is a sequence of images in YUV 4:2:2 format received from the camera subsystem.

- Write actual image received from the camera subsystem into SDRAM through the VRFB in the first view (0°).
- Display the image in SDRAM on the external display through the display subsystem in any of the four available VRFB views (0°, 90°, 180°, or 270°).

See [Figure 11-66](#) for the VRFB data path of this use case.

The row increment in the SDRAM is programmed in the display subsystem registers and depends on the VRFB rotation angle.

### 11.2.6.4.4 Programming Flow

A main function automatically configures the VRFB contexts. This function is called four times to configure each of the four contexts. For each context, a set of parameters is given to the function:

- The actual image width and height (from the camera subsystem)
- The physical address (of the given context)

- The rotation of the context

The main function initializes the VFRB in three steps:

1. Virtual frame buffer configuration. This is done with a page size calculation function, as described in [Section 11.2.6.4.4.1](#).
2. Image size configuration. This is done with a picture size calculation function, as described in [Section 11.2.6.4.4.2](#).
3. Physical base address configuration, as described in [Section 11.2.6.4.4.3](#).

#### 11.2.6.4.4.1 Page Size Calculation Function

The page size is configured through three parameters: page width (PW), page height (PH), and pixel size (PS). The three page size parameters are configured into the `SMS_ROT_CONTROLn` registers, where `n` is the context number (`n = 0 to 3`):

- Page width: `SMS_ROT_CONTROLn[6:4]` PW. The PW parameter defines the page width according to the value of  $2^{PW}$  bytes.
- Page height: `SMS_ROT_CONTROLn[10:8]` PH. The PH parameter defines the page height according to the value of  $2^{PH}$  lines.
- Pixel format: `SMS_ROT_CONTROLn[1:0]` PS. The PS parameter defines the pixel size according to the value of  $2^{PS}$  bytes. In this use case, the pixel size is a constant linked to the YUV 4:2:2 format. For more details about YUV 4:2:2 format, see [Section 11.2.6.1.2, Setting a VFRB Context](#).

The recommendation is to have a squared page arrangement. The page can be defined as a 32-byte x32-byte array (1024-byte page) or 16-byte x16-byte array (256-byte page). This arrangement is pixel-based, which means the pixel size must be part of the calculation. Other settings are possible, but from a performance point of view it is recommended to have the page size consistent with the SDRAM page.

In this use case, however, the page size calculation function defines the page width and the page height. The pixel size is not part of the calculation. Hence, instead of having a 64 x32 page (because a pixel takes 2 bytes) the function calculates a 32 x32 page. This gives a page size of 1K-byte, and memory area usage is optimized.

First, the function checks whether the width of the image received from the camera is a multiple of 32 bytes. If the width is not a multiple of 32 bytes, the function checks whether the image is a multiple of 16 bytes. If the image from the camera is neither a multiple of 32 bytes nor 16 bytes, the function sets the page width to 32 bytes as the default. In this use case, the image received from the camera has a width of 736 pixels.

1. Check that 736 is a multiple of 32:  $736 / 32 = 23$ . It is. As a consequence, the page width is 32 (bytes).
2. Configure a page width of 32 with the  $2^{PW}$  bytes formula: `SMS_ROT_CONTROLn[6:4]` PW = 0x5.

Then, the function checks whether the height of the image received from the camera is a multiple of 32 (rows). If the height is not a multiple of 32 (rows), the function checks whether the image is a multiple of 16 rows. If the image from the camera is neither a multiple of 32 rows nor 16 rows, the function sets the page height to 32 rows as the default. In this use case, the image received from the camera has a height of 560 lines.

3. Check that 560 is a multiple of 32:  $560 / 32 = 17.5$ . It is not.
4. Check that 560 is a multiple of 16:  $560 / 16 = 35$ . It is. As a consequence, the page height is 16 (lines).
5. Configure a page height of 16 with the  $2^{PH}$  lines formula: `SMS_ROT_CONTROLn[10:8]` PH= 0x4.  
The pixel format of this use case is YUV 4:2:2. Two pixels are stored on 4 bytes.
6. Configure a pixel size of 4 bytes with the  $2^{PS}$  bytes formula: `SMS_ROT_CONTROLn[1:0]` PS = 0x2.

#### 11.2.6.4.4.2 Picture Size Calculation Function

The picture size is configured through two parameters: image width (IMAGEWIDTH) and image height (IMAGEHEIGHT). Two sizes must be distinguished:

- Actual image width and actual image height. This is the size of the image received by the camera subsystem.
- Programmed image width and programmed image height. This is the size of the image programmed in

the VRFB.

Figure 11-82 shows the actual image width (IW) and image height (IH) versus the programmed image width ( $IW + \Delta IW$ ) and programmed image height ( $IH + \Delta IH$ ).

**Figure 11-82. VRFB Actual Image Size vs Programmed Image Size**

sdr-040

The programmed image size parameters are configured into the `SMS_ROT_SIZEn` registers, where *n* is the context number (*n* = 0 to 3):

- Image width: `SMS_ROT_SIZEn[10:0] IMAGEWIDTH`. This parameter is expressed in the number of pixels.
- Image height: `SMS_ROT_SIZEn[26:16] IMAGEHEIGHT`. This parameter is expressed in the number of pixels.

The picture size calculation function determines the required number of pages per line and per column using the page size calculated previously. That is a page width of 8 pixels (32 bytes and 4-byte pixel) and a page height of 16 pixels.

1. Determine the required number of pages per line with the formula:  

$$\left[ \left( \frac{\text{actual\_image\_width}}{2} \right) \text{ pixels} / \text{page\_width bytes} \right] \times \text{pixel\_size bytes/pixel}$$
 This gives a required number of pages per line of  $\left[ (736 / 2) / 32 \right] \times 4 = 46$ .  
 If the number of pages per line is not an integer, it must be rounded up; for instance, if the result was 46.25 the number of pages required per line would be 47. Figure 11-82 shows this point.
2. Determine the required number of pages per column with the formula:  

$$\frac{\text{actual\_image\_height pixels}}{\text{page\_height lines}}$$
 This gives a required number of pages per column of  $(560) / 16 = 35$ .  
 If the number of pages per column is not an integer, it must be rounded up.

Finally, calculate the programmed image size in pixels using the number of pages calculated above:

1. Calculate the programmed image width with the formula:  

$$\left( \text{rounded\_up\_number\_of\_pages\_per\_line} \times \text{page\_width bytes} \right) / \text{pixel\_size bytes/pixel}$$
 This gives a programmed image width of  $(46 \times 32) / 4 = 368$ .  
 The function sets `SMS_ROT_SIZEn[10:0] IMAGEWIDTH = 0x170`.
2. Calculate the programmed image height with the formula:  

$$\left( \text{rounded\_up\_number\_of\_pages\_per\_column} \times \text{page\_height lines} \right)$$
 This gives a programmed image height of  $(35 \times 16) = 560$ .  
 The function sets `SMS_ROT_SIZEn[26:16] IMAGEHEIGHT = 0x230`.

Because the actual image is a multiple of the page size (both width and height, as explained in [Section 11.2.6.4.4.1](#)), the actual image size and the programmed size are the same. In other words,  $\Delta IW$  and  $\Delta IH$  are null in this use case.

#### 11.2.6.4.4.3 Physical Base Address Configuration

The physical base address is the address of the picture in the external SDRAM. In this use case, the address space of CS0 is 512 Mbits, ranging from 0x8000 0000 to 0x83FF FFFF because the Mobile DDR SDRAM used in example is a 512 Mbits memory device.

The physical address of the image is a parameter entered by the user. It is directly written into the [SMS\\_ROT\\_PHYSICAL\\_BAn](#)[30:0] PHYSICALBA bit field (where n = 0 to 11, for the 12 contexts).

#### 11.2.6.4.4.4 VRFB Use Case Summarizing Register Values

[Table 11-114](#) summarizes all the VRFB registers to be configured with the required values.

**Table 11-114. VRFB Use Case Summarizing Register Print**

Register Name	Context Number n	Physical Address	Value	Value Description
<a href="#">SMS_ROT_CONTROLn</a>	0	0x6C00 0180	0x0000 0452	The page size is 8-pixel wide and 16-pixel high. This is a width of 32 bytes and a height of 16 lines. The pixel format is YUV 4:2:2 (2 pixels take 4 bytes).
	1	0x6C00 0190		
	2	0x6C00 01A0		
	3	0x6C00 01B0		
<a href="#">SMS_ROT_SIZEEn</a>	0	0x6C00 0184	0x0230 0170	Actual image size is 736 x560. This gives 368 x560 with the YUV 4:2:2 pixel format
	1	0x6C00 0194		
	2	0x6C00 01A4		
	3	0x6C00 01B4		
<a href="#">SMS_ROT_PHYSICAL_BAn</a>	0	0x6C00 0188	0x8090 0000	Example of physical base address
	1	0x6C00 0198	0x8100 0000	
	2	0x6C00 01A8	0x8190 0000	
	3	0x6C00 01B8	0x8200 0000	

### 11.2.6.5 Understanding SDRAM Subsystem Address Spaces

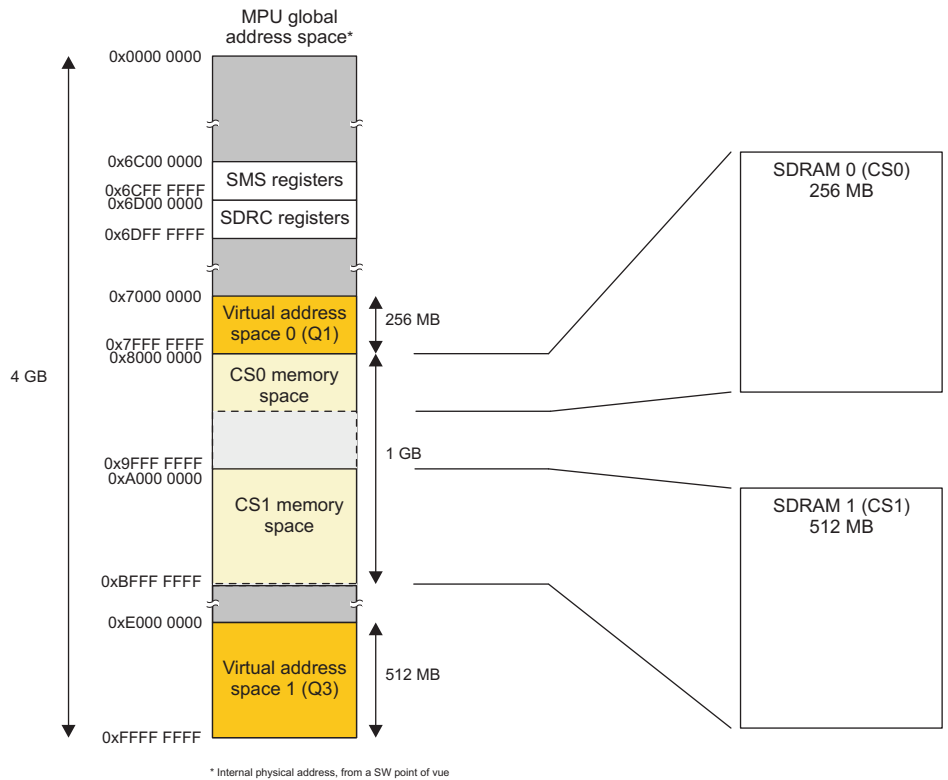

#### 11.2.6.5.1 Physical vs Virtual Address Spaces

One thing that the SMS does is to translate virtual addresses into physical SDRAM addresses in case of rotation only; that is, when accessing virtual address space 0 (quarter 1) and virtual address space 1 (quarter 3) as shown in [Figure 11-83](#). The SMS then reinserts a request, or multiple requests depending on the SMS parameters, in the SMS request path to the SDRC (through the VRFB or not).

The SDRAM subsystem global memory space mapping reaches 1.768G-bytes:

- 1G-byte of CS memory space (CS0 and CS1 memory spaces): the SDRC automatically accesses the two external memory devices through direct accesses (addresses are simply translated).
- 768M-bytes of virtual address space (address space 0 and address space 1): the SDRC automatically accesses the two external memory devices through re-organized access (requests are modified accordingly to the context number and rotation angle before address translation). See [section 11.2.6.5.1.2](#) for more information on VRFB contexts and rotation angles.

**Figure 11-83. SDRC Address Space in MPU Global Address Space**

Configuration register space is detailed in [Table 11-115](#).

**Table 11-115. SDRC and SMS Configuration Register Space**

Module	Start Address	End Address	Total Space
SMS	0x6C00 0000	0x6CFF FFFF	16 MB
SDRC	0x6D00 0000	0x6DFF FFFF	16 MB

### 11.2.6.5.1.1 Physical Address Space

The physical address space of the SDRC is 1G byte (maximum addressing capability).

The SDRC has a memory device capacity of 16M bits to 2G bits. The smallest granularity of supported memory device is 16M bits/2M bytes.

### 11.2.6.5.1.2 Virtual Address Space

The SDRC-SMS virtual memory space is a memory space used to access a subset of the SDRC memory space through the rotation engine (VRFB). The virtual address space size is 768M bytes split into two parts: the first 256M-byte part is in the second quarter (Q1) of the memory; the second 512M-byte part is in the fourth quarter (Q3) of the memory. See [Chapter 2, Memory Mapping](#), for more information on global memory mapping.

The VRFB is a rotation engine that:

- Supports rotations of 0, 90, 180, and 270 degrees
- Can handle up to 12 concurrent rotation contexts

The VRFB has therefore 48 different contexts in the virtual address space. [Table 11-116](#) gives the VRFB address-space memory locations at which the frame buffer object can be accessed. The table summarizes the virtual addresses of all 48 available image buffer from a global memory space (top level) point of view.

**Table 11-116. VRFB Contexts vs Rotation Angle**

Context Number	0°	90°	180°	270°
0	0x7000 0000	0x7100 0000	0x7200 0000	0x7300 0000
1	0x7400 0000	0x7500 0000	0x7600 0000	0x7700 0000
2	0x7800 0000	0x7900 0000	0x7A00 0000	0x7B00 0000
3	0x7C00 0000	0x7D00 0000	0x7E00 0000	0x7F00 0000
4	0xE000 0000	0xE100 0000	0xE200 0000	0xE300 0000
5	0xE400 0000	0xE500 0000	0xE600 0000	0xE700 0000
6	0xE800 0000	0xE900 0000	0xEA00 0000	0xEB00 0000
7	0xEC00 0000	0xED00 0000	0xEE00 0000	0xEF00 0000
8	0xF000 0000	0xF100 0000	0xF200 0000	0xF300 0000
9	0xF400 0000	0xF500 0000	0xF600 0000	0xF700 0000
10	0xF800 0000	0xF900 0000	0xFA00 0000	0xFB00 0000
11	0xFC00 0000	0xFD00 0000	0xFE00 0000	0xFF00 0000

The physical address of a page is calculated with the formula:

$$\text{Physical address} = \text{Physical base address} + \text{Base address of page} \quad (1)$$

where *Physical base address* is defined through the [SMS\\_ROT\\_PHYSICAL\\_BAn\[30:0\]](#) PHYSICALBA field (buffer physical base address on which the rotation occurs), and *Base address of page* is the address obtained in the function of the context number and rotation angle, as given in [Table 11-116](#).

#### 11.2.6.5.2 CS Memory Spaces

Two SDRC chip-selects (sdrnc\_0 and sdrnc\_1) are available to access two external SDRAM memories.

##### 11.2.6.5.2.1 SDRAM Capacity Calculation

This section aims to explain how to calculate an SDRAM device capacity.

From the following SDRAM characteristics:

- Four banks: BA0–BA1
- Row addresses: A0–A12
- Column addresses: A0–A9
- 16-bit data bus to external memory

First calculate the number of addressable locations:

- Number of address lines: 13 (A0-A12)
- Number of banks address lines: 2 (BA0-BA1)
- Maximum number of rows = 13 (number of address lines used for row decoding)
- Maximum number of columns = 10 (number of address lines used for column decoding)

$$\text{Total locations in a bank} = (2^{13}) \times (2^{10}) \quad (2)$$

Then calculate the total locations in the device:

$$\text{Total locations in the device} = (\text{Number of banks}) \times (\text{Total locations in a bank}) = (2^2) \times (2^{13} \times 2^{10}) = 2^{25} \quad (3)$$

Finally calculate the SDRAM device capacity:

$$\text{Total device capacity} = (\text{Total locations in the device}) \times (\text{Device organization}) = (2^{25}) \times (16) = 2^{29} \text{ bits} \quad (4)$$

Hence, the device has a maximal capacity of 512M bits (or 64M bytes).

In the same way, the SDRC maximal capacity can be calculated as follow:

- Number of address lines: 15 (A0-A14)
- Maximum number of rows = 15 (limited by the number of address lines, hence do not program

[SDRC\\_MCFG\\_p\[26:24\]](#) RASWIDTH above 15)

- Maximum number of columns = 12 (limited by [SDRC\\_MCFG\\_p\[22:20\]](#) CASWIDTH)
- Data bus width to external device: 32-bit

SDRC total capacity =  $(2^{15} \times 2^{12}) \times 32 = 4\text{G bits}$  (or 512M bytes)

(5)

Hence, the SDRC has a maximum addressing capability of 8G bits/1G byte (as seen in [Section 11.2.6.5.1.1](#)) and can manage SDRAM devices with capacity of up to 4G bits/512M bytes.

### 11.2.6.5.2.2 CS Size

Each chip-select has its programmable size. The CS size is expressed in [SDRC\\_MCFG\\_p\[17:8\]](#) RAMSIZE ( $p = 0$  or  $1$  for CS0 or CS1) as a number of 2M-byte chunks.

For instance, when connecting a 256M-bit SDRAM memory (see the mux scheme MUX7 in [Table 11-96](#)) to the SDRC, RAMSIZE must be set with the value 0x010 (32M bytes = 2MB  $\times$  16).

### 11.2.6.5.2.3 CS Start and End Addresses

See [Figure 11-84](#), *CS0/CS1 Chip-Select Start Address Slots*, for a graphical representation of CS starts addresses and CS size.

CS0 start address is fixed at :

- 0x0000 0000 from an SDRC point of view
- 0x8000 0000 from a global memory space point of view.

Therefore, when connecting a 256M bit/32M-byte SDRAM memory (16M  $\times$  8 such as in MUX6, [Table 11-96](#)), the CS0 end address is 0x0200 0000 (SDRC point of view).

CS1 start address is programmable and its default value is :

- 0x2000 0000 from an SDRC address point of view
- 0xA000 0000 from a global memory space point of view.

The SDRC 1G-byte address space is segmented into eight 128M-byte address spaces, which are themselves segmented into four 32M-byte address spaces so that 32 possible CS1 start address locations are defined, as shown in [Figure 11-84](#). The first 32M-byte address space of the first 128M-byte address space is reserved for CS0 (address 0x0000 0000). Any other address can be used as the CS1 start address. To define a CS1 start address, set the [SDRC\\_CS\\_CFG\[9:8\]](#) CS1STARTLOW and [SDRC\\_CS\\_CFG\[3:0\]](#) CS1STARHIGH fields as follows:

- [SDRC\\_CS\\_CFG\[3:0\]](#) CS1STARHIGH corresponds to one of the eight 128M-byte address spaces (total address space of SDRC is 1G-byte): 0x0000 for the first partition up to 0x0111 for the eighth partition. The [SDRC\\_CS\\_CFG\[3\]](#) must always be set to 0.
- [SDRC\\_CS\\_CFG\[9:8\]](#) CS1STARTLOW corresponds, for a given 128M-byte address space, to one of the four 32M-byte address spaces: 0x00 for the first, up to 0x11 for the fourth.

Therefore, for a start address of 0x2000 0000 (SDRC point of view) when connecting a 2048-Mbit SDRAM memory (64M  $\times$  32 such as in MUX25, [Table 11-97](#)), the [SDRC\\_CS\\_CFG\[9:8\]](#) CS1STARTLOW bit field must be set to 0x00 (the first 32M-byte address space, as shown in [Figure 11-84](#)), and the [SDRC\\_CS\\_CFG\[3:0\]](#) CS1STARHIGH bit field must be set to 0x0100 (fourth 128M-byte address space). The start address must be aligned on the memory size.

The CS1 end address (0x3000 0000) can be deduced from the CS1 size ( that is, from the RAMSIZE parameter), which takes the value 0x80 when connecting a 2048-Mbit SDRAM memory.

Figure 11-84. CS Start and End Address Configuration Example

### 11.2.6.6 How to Choose a Suitable SDRAM

This section describes how to select a suitable SDRAM device to interface with the SDRC. Basically, if an SDRAM device is aligned with the JEDEC LPDDR1 SDRAM standard (JEDEC committee JC42.3), the SDRAM device is likely to be compatible with the SDRC. To ensure that an SDRAM device is fully compatible, see the following sections.

[Section 11.2.6.6.1](#) discusses the SDRAM device features to consider. [Section 11.2.6.6.2](#) discusses the SDRC features to consider. As an example, [Section 11.2.6.6.3](#) lists chosen SDRAM parameters versus the supported characteristics of the SDRC.

#### 11.2.6.6.1 SDRAM Device Parameters

Several settings must be considered when selecting an SDRAM device to interface with the SDRC:

- SDRAM type
- Operating voltage
- Maximum operating frequency
- Maximum memory size
- Memory organization:

- Number of banks
- Data bus width
- Burst length
- Page size
- Column address strobe (CAS) latency
- Refresh rate
- AC timing parameters and especially the access time parameter tAC

These parameters are defined in the SDRAM device datasheet and must meet the SDRC specifications.

#### 11.2.6.6.2 SDRC Characteristics

Keeping the SDRAM device settings in mind, the SDRC supports:

- Supported device type: Up to two mobile single data rate (M-SDR) SDRAMs, or up to two low-power double data rate (LPDDR) SDRAMs.
- Maximum supported memory size: 128MB per external SDRAM bank (256-MB and 512-MB SDRAM may be supported, depending on their implementation)
- Minimum supported memory size: 2MB
- Maximum SDRC addressing capability: 1GB
- Memory organization:
  - Number of internal SDRAM banks: two (for 2-MB and 4-MB memory devices only) or four banks (other memory device only)
  - Data path to external SDRAM memory: 16-or 32-bit
- Burst Length: Burst of 2 (M-SDR) and burst of 4 (LPDDR)
- Page size: Programmable value (up to 16KB)
- Column address strobe latency (CL): 1 to 5 system clock cycles
- Refresh intervals: Programmable value
- Major operation is 3-3-3 (CL-tRCD-tRP) conditions.
  - CL = 3
  - tRCD = 3 clocks cycle time
  - tRP = 3 clocks cycle time
  - tRRD = 2 clocks cycle time
  - tRAS = 7 clocks cycle time
  - tRC = 10 clocks cycle time

#### 11.2.6.6.3 SDRAM Device Compatibility Verification

In this example, a mobile DDR SDRAM memory with the following characteristics is verified for compatibility:

- Type: Mobile DDR SDRAM
- Size: 512 Mbits (16M x 32 in 4 banks)

Table 11-117 lists the SDRAM versus the SDRC characteristics.

**Table 11-117. SDRAM vs SDRC Characteristics**

SDRAM Parameter	SDRC	512-Mbit MDDR SDRAM (16M x 32)	Compatibility
Device type	Mobile SDR / low-power DDR	Low-power DDR	✓

**Table 11-117. SDRAM vs SDRC Characteristics (continued)**

SDRAM Parameter	SDRC	512-Mbit MDDR SDRAM (16M x 32)	Co mpa tibili ty
Operating voltage	VDD = VDDQ = 1.7V to 1.9V; VSS = VSSQ = 0.0V (and LVCMOS 1.8V I/Os)	0.8xVDDQ ≥ High level ≤ VDDQ + 0.3V -0.3V ≤ Low level ≤ 0.2 x VDDQ 1.8V ≤ I/O power ≤ 1.95V	✓
Max operating frequency	166 MHz	166 MHz (DDR333)	✓
Memory size	Min: 16 Mbits, max: 1024M bits (2048 and 4096M bits may be supported)	512M bits	✓
Number of banks	2 (16 and 32 Mb) or 4 (other)	4	✓
Data path SDRC/SDRAM	16- and 32-bit	32-bit	✓
Burst length	Burst of 2 (M-SDR) and Burst of 4 (LPDDR)	2, 4, 8	✓
Page size	Up to 16KB	2KB	✓
CAS latency	1 to 5 clock cycles	3	✓
Refresh interval	64ms / number of rows	7.8 μs	✓

## 11.2.7 SMS Register Manual

### 11.2.7.1 SMS Instance Summary

Table 11-118 describes the SMS module instance.

**Table 11-118. SMS Instance Summary**

Module Name	Base Address	Size
SMS	0x6C00 0000	64K bytes

### 11.2.7.2 SMS Register Summary

Table 11-119 summarizes the SMS register mapping summary.

<b>Address Offset</b>	0x0000 0174	<b>Instance</b>	SMS
<b>Physical Address</b>	0x6C00 0174		
<b>Description</b>	This register provides additional information about the access that has generated the error.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED				ERRORREGIONID				RESERVED	ERRORMCMD				ERRORCONNID				RESERVED				UNEXPECTEDADD	UNEXPECTEDREQ	ILLEGALCMD	RESERVED				ERRORSECOVERLAP	RESERVED	RESERVED	ERRORVALID

Bits	Field Name	Description	Type	Reset
31:27	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00
26:24	ERRORREGIONID	ID of the region that has been illegally accessed 0x0: Region 0 0x1: Region 1 ... 0x7: Region 7 0x8 to 0xF: reserved	R	0x0
23	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
22:20	ERRORMCMD	Interconnect command that caused the error	R	0x0
19:16	ERRORCONNID	Identifies the illegal access initiator interconnect ConnID of the illegal access initiator. Refer to the top level documentation of the device using the SMS module	R	0x0
15:11	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00

Bits	Field Name	Description	Type	Reset
10	UNEXPECTEDADD	Request targeting non-defined rotation contexts (such as contexts 12, 13, 14, or 15) or non-defined L3 Interconnect request signals used for context number decoding.  Read 0x0: No unexpected request received Write 0x0: No effect  Read 0x1: A request has been received on the interconnect with address decoding targeting rotation contexts 12, 13, 14, or 15, or a signal used for context number decoding was undefined. Write 0x1: Clear UNEXPECTEDADD bit.	RW	0x0
9	UNEXPECTEDREQ	Unexpected request received during SMS idle state  Read 0x0: No unexpected request received Write 0x0: No effect  Read 0x1: A request has been received on the interconnect after the SMS was put in idle mode by the system power manager. Write 0x1: Clear the UNEXPECTEDREQ bit field.	RW	0x0
8	ILLEGALCMD	Illegal command on the L3 interface  Read 0x0: No illegal command received Write 0x0: No effect  Read 0x1: Illegal command has been received. Write 0x1: Clear ILLEGALCMD bit field.	RW	0x0
7:4	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
3	ERRORSECOVERLAP	Protection region overlapping error  Read 0x0: No overlap violation detected Write 0x0: No effect  Read 0x1: A protection region overlap violation has been detected. Write 0x1: Clear ERRORSECOVERLAP bit field.	RW	0x0
2	RESERVED	Reserved for non-GP devices.	RW	0x0
1	RESERVED	Reserved for non-GP devices.	RW	0x0
0	ERRORVALID	Error validity status - Must be explicitly cleared with a write transaction  Read 0x0: No effect Write 0x0: All error fields no longer valid  Read 0x1: Error detected and logged in the other error fields Write 0x1: Clear ERRORVALID bit field	RW	0x0

**Table 11-174. SDRC\_DLLA\_CTRL**

<b>Address Offset</b>	0x0000 0060	<b>Instance</b>	SDRC
<b>Physical Address</b>	0x6D00 0060		
<b>Description</b>	This register controls the SDRC DLL A resource used for fine timing tuning on a double-data-rate interface.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FIXEDELAY								MODEFIXEDELAYINITLAT								RESERVED								WRITEDDRCLKX2DIS	DLLMODEONIDLEREQ	DLLIDLE	ENADLL	LOCKDLL	DLLPHASE	RESERVED	

Bits	Field Name	Description	Type	Reset
31:24	FIXEDELAY	Phase offset value in ModeFixedDelay mode. Maximum frequency supported in this mode is 83 MHz. FIXEDELAY steps are defined after DLL cell characterization.	RW	0x00
23:16	MODEFIXEDELAYINITLAT	Initial latency before first request to be processed in ModeFixedDelay mode <sup>(1)</sup> 0x0: no initial latency before first access 0x1: 2 clock cycles before first access 0x2: 4 clock cycles before first access 0x3: 6 clock cycles before first access 0x4 : 8 clock cycles before first access ... 0xFF: 510 clock cycles before first access	RW	0x00
15:8	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x00
7	WRITEDDRCLKX2DIS	Disable MDDR write path using the double frequency input clock. 0x0: MDDR write path using the double frequency clock logic 0x1: MDDR write path using the DLL/CDL write path logic	RW	0x0
6:5	DLLMODEONIDLEREQ	Selects the DLL mode upon hardware idle request 0x0: DLL in Power-down mode upon hardware idle request 0x1: DLL in DLL idle mode upon hardware idle request 0x2: No action upon hardware idle request. Input clock frequency must not be changed. 0x3: Reserved for future use (no action upon hardware idle request).	RW	0x0
4	DLLIDLE	Enables the DLL Idle mode 0x0: DLL Idle mode disabled 0x1: DLL Idle mode enabled	RW	0x0
3	ENADLL	Enables DLL 0x0: DLL disabled 0x1: DLL enabled	RW	0x0

<sup>(1)</sup> The DLL characterization shows that this feature is not useful and that this value must be left at 0x0.

Bits	Field Name	Description	Type	Reset
2	LOCKDLL	Selects the DLL functionality between the TrackingDelay mode (previously called lock mode) or the ModeFixedDelay mode (previously called unlock mode). The DLL mode is updated in the DLL cell after: - DLLIDLE mode - DLL power-down mode  0x0: LOCKDLL at 0 puts the DLL in TrackingDelay mode (tracking counter started).  0x1: LOCKDLL at 1 puts the DLL in ModeFixedDelay mode. The fixed delay defined in FIXEDDELAY bit field is used to delay DQS lines for read accesses.	RW	0x0
1	DLLPHASE	Nominal digitally-controlled delay when DLL is enabled  0x0: 72 degrees (20% of the clock period)  0x1: 90 degrees (25% of the clock cycle)	RW	0x0
0	RESERVED	Write 0s for future compatibility. Reads return 0.	RW	0x0

<b>Address Offset</b>	0x0000 0070	<b>Instance</b>	SDRC
<b>Physical Address</b>	0x6D00 0070		
<b>Description</b>	This SDRC power-management register defines the global power-management policy (shared by CS0/CS1).		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED						WAKEUPPROC	RESERVED	AUTOCOUNT										SRFRONRESET	SRFRONIDLEREQ	CLKCTRL	EXTCLKDIS	PWDENA	RESERVED	PAGEPOLICY							

Bits	Field Name	Description	Type	Reset
31:27	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x00
26	WAKEUPPROC	Select if after a SDRC wakeup in DDR mode (in DLL tracking-delay mode), the first request is stalled during 500 cycles latency or until the lock signal from the DLL/CDL analog cell is asserted.  0x0: SDRC allows DDR access after 500 L3 clock cycles. 0x1: SDRC allows DDR access as soon as DLL LOCKSTATUS bit is 1.	RW	0x0
25:24	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0
23:8	AUTOCOUNT	16-bit programmable count value used for delayed automatic clock gating and self-refresh entry, assuming CLKCTRL field is not 0	RW	0x0000
7	SRFRONRESET	Enter self refresh when a warm reset is applied: 0x0: Feature disabled 0x1: Feature enabled	RW	0x1
6	SRFRONIDLEREQ	Enter self refresh when on hardware idle request: 0x0: Feature disabled 0x1: Feature enabled	RW	0x0
5:4	CLKCTRL	Clock control feature defines clock gating and self refresh: 0x0: No auto clk feature turned on 0x1: Enable internal clock gating on timeout of Auto_cnt 0x2: Enable self-refresh on timeout of Auto_cnt 0x3: Reserved	RW	0x0
3	EXTCLKDIS	Disable the clock provided to the external memories: 0x0: Enable clock 0x1: Disable clock- Logical 0 is applied.	RW	0x0
2	PWDENA	Activate the power-down mode of the target memory through CKE pin. 0x0: Power-down mode feature disabled 0x1: Power-down mode feature enabled	RW	0x1
1	RESERVED	Write 0 for future compatibility. Read returns 0.	RW	0x0

Bits	Field Name	Description	Type	Reset
0	PAGEPOLICY	Page/segment closure policy with respect to power versus bandwidth trade-off - Must be set to 1  0x0: Reserved - must not be used 0x1: High-power/high bandwidth mode (HPHB)	RW	0x1

<b>Description</b>	This 12-bit register corresponds to the low-power EMR register, as defined in the mobile DDR JEDEC Standard. All 12 bits are loaded into the memory, thus assuring future extension support. The SDRC keeps an internal copy register used internally; that is, returned when a read access is performed at that address. Load into memory on interconnect write access using MRS command with BA1,BA0 = 1,0.

### 11.3 On-Chip Memory Subsystem

#### 11.3.1 OCM Subsystem Overview

The on-chip memory subsystem consists of two separate on-chip memory controllers, one connected to an on-chip ROM (OCM\_ROM) and the other connected to an on-chip RAM (OCM\_RAM). Each memory controller has its own dedicated interface to the L3 interconnect.

Figure 11-85 is an overview of the OCM subsystem.

Figure 11-85. OCM Subsystem Overview

Ocm-003

Multiple L3 initiators (such as remote devices) have access to the RAM through 2D/3D graphics, the MPU subsystem, sDMA, the camera subsystem, the display subsystem, IVA2, and USB.

ROM is used for direct boot code and boot from external NAND flash.

## 11.3.2 OCM Subsystem Integration

### 11.3.2.1 Description

The OCM\_ROM and OCM\_RAM allow transactions between the system initiators and the multiple memories, through the L3 interconnect.

Figure 11-86 shows the integration of the OCM subsystem to the OMAP processor.

**Figure 11-86. OCM Subsystem Integration to the Device**

Ocm-004

### 11.3.2.2 Clocking, Reset, and Power-Management Scheme

#### 11.3.2.2.1 Clocking

The on-chip boot ROM and RAM are clocked only when they are accessed.

The interface clock OCM\_CLK comes from the PRCM module and runs at the L3 interconnect frequency. The OCM\_CLK source is PRCM CORE\_L3\_ICLK output. This clock is also used as the functional clock for the OCM module.

For the OCM subsystem, no register enables the gating of OCM\_CLK.

However, OCM does support the handshaking protocol with the PRCM module. It is not programmable by software. The following signals support the handshaking protocol for ROM and RAM devices:

- OCMROM\_IDLEREQ/OCMROM\_SIDLEACK (for ROM devices)
- OCMRAM\_IDLEREQ/OCMRAM\_SIDLEACK (for RAM devices)

OCM\_CLK is gated if all modules (including the OCM) belonging to the L3 CLK domain send a SidleAck back to the PRCM module after reception of the MidleReq request.

For details, see [Chapter 4, Power, Reset, and Clock Management](#).

When the memory is not accessed by the system, the module performs automatic clock gating. Because the clock to the memory is dynamically gated, there is no extra latency when the clock must be switched on after an idle state.

#### 11.3.2.2.2 **Hardware Reset**

Global reset of the module is performed by activation of the CORE\_RST in the core reset domain (see [Chapter 4, Power, Reset, and Clock Management](#)).

#### 11.3.2.2.3 **Power Domain**

OCM power is supplied by the CORE power domain (see [Chapter 4, Power, Reset, and Clock Management](#)).

### 11.3.3 **OCM Subsystem Functional Description**

#### 11.3.3.1 **OCM\_ROM**

The embedded ROM is used primarily for booting, flashing, and context restoring.

The device-embedded ROM (total 32K bytes) has the following characteristics:

- The OCM\_ROM is always accessible, and contains the boot area.
- The OCM\_ROM supports single and burst access transactions.
- The OCM\_ROM operates at full interconnect clock frequency.
- The COM\_ROM needs three cycles for initial access and one cycle per subsequent access.

The memory space of the embedded ROM starts at 0x4001 4000 and ends at 0x4001 BFFF.

#### 11.3.3.2 **OCM\_RAM**

By default, only 2K bytes are available after reset; however, the configuration can then be changed to adapt to booting/flashing, normal boot, or to any application requirement.

The device-embedded RAM has the following characteristics:

- Operates at full L3 interconnect clock frequency
- Fully pipelined, one 32-bit access per cycle
- Restricted access support, based on:
  - A region-based partitioning (see the L3 firewall description)
  - The module owner of the access, with respect to its read and write permission to that region
  - The transaction attributes of the access, with respect to the region permission properties:
    - User/supervisor
    - Code/data access

The OCM\_RAM can be partitioned using the L3 firewall and used as RAM for a video frame buffer or to any application.

The RAM memory space starts at 0x4020 0000 and ends at 0x4020 FFFF.

## Camera ISP

---

---

---

This chapter describes the camera subsystem with the image signal processor (ISP) feature.

---

**NOTE:** Some features may not be available or supported in your particular device. For more information, see Chapter 1, the Device Family section, and your device-specific data manual.

---

## 12.1 Camera ISP Overview

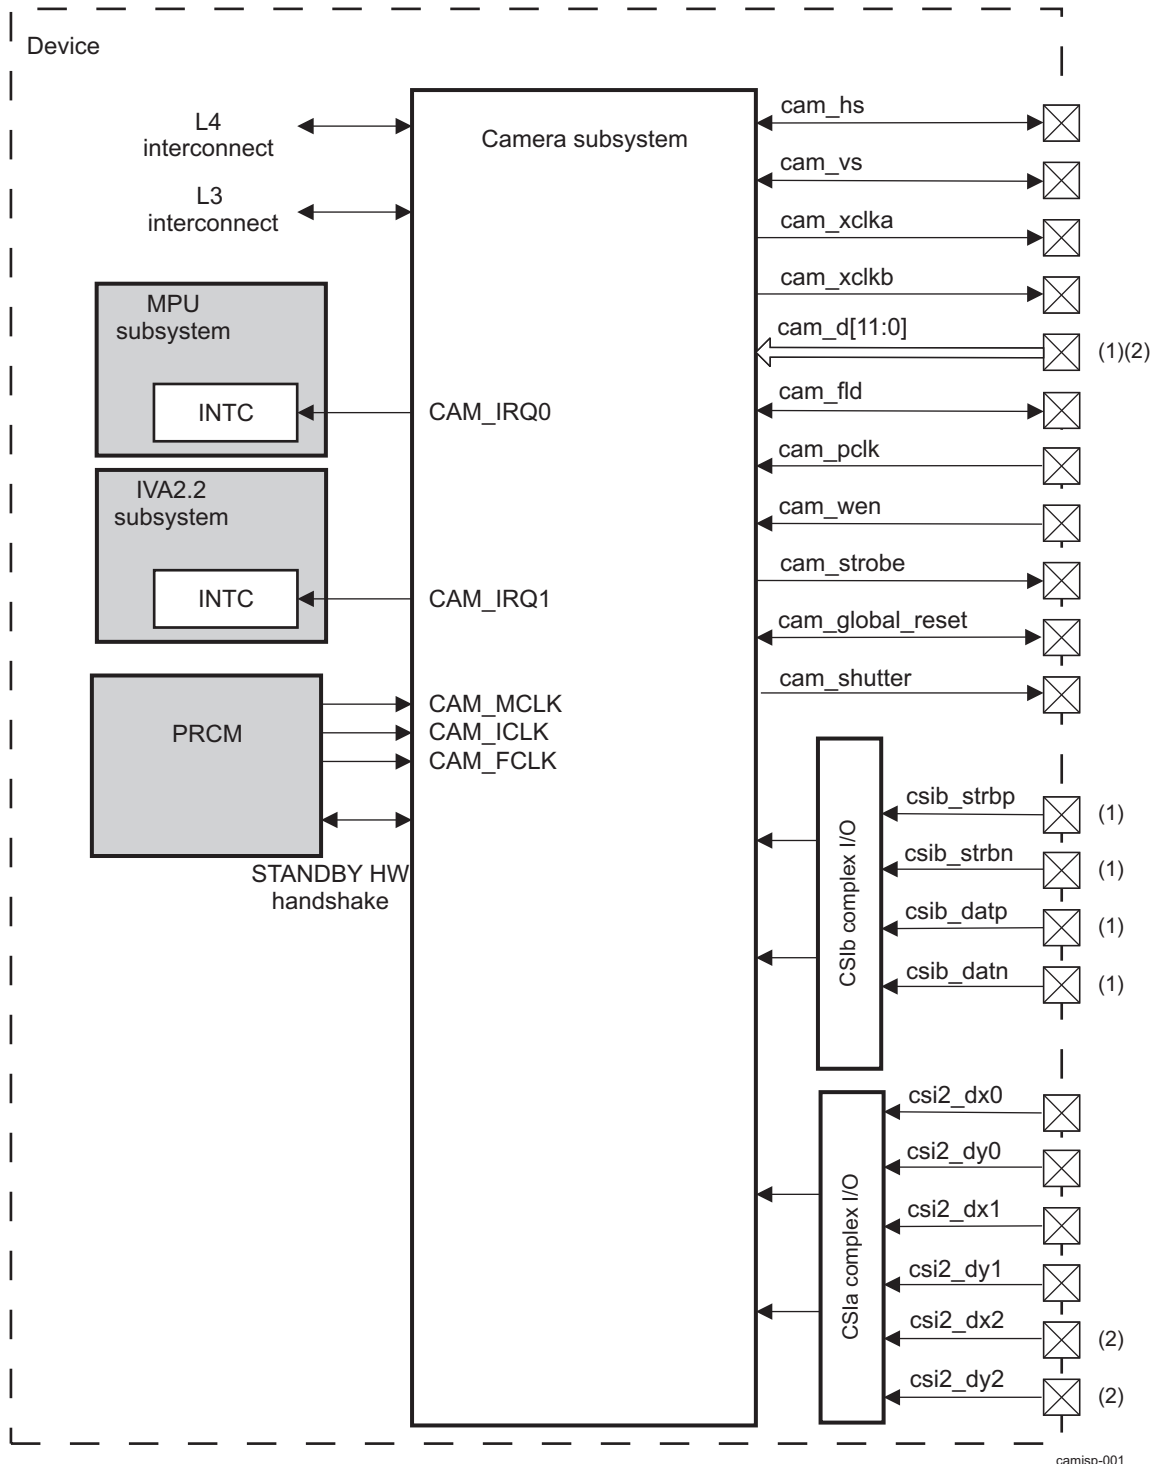

The camera ISP is a key component for imaging and video applications such as video preview, video record, and still-image capture with or without digital zooming.

The camera ISP provides the system interface and the processing capability to connect RAW image-sensor modules to the device.

The camera ISP supports one parallel interface (CPI) and two serial interfaces: MIPI® CSI1 and one MIPI CSI2 interface, that can be active simultaneously. However, only one of these interfaces can use the video-processing hardware, when it is not used by the parallel interface. Because of a pin-muxing limitation, the parallel interface and CSI1 (CS1b) cannot be active at the same time.

[Figure 12-1](#) shows the camera ISP.

Figure 12-1. Camera ISP Highlight

- (1) There is no mux control bit. If the CS1b interface is enabled, the cam\_d6 to cam\_d9 pins are used by the CS1b interface.
- (2) These signals are muxed. They are controlled by the CONTROL\_PADCONF\_CAM\_FLD and CONTROL\_PADCONF\_CAM\_D1 registers.

camisp-001

---

**NOTE:** For more information about initializing and configuring the complex I/Os, see [Section 12.5.1, Programming the CSI1 or CSI2 Receiver Associated Complex I/O](#).

---

### 12.1.1 Camera ISP Features

The camera ISP can support the following features:

- **Image sensor:**
  - Interface with various image sensors:
    - R, G, B primary colors
    - Ye, Cy, Mg, G complementary colors
  - Support for electronic rolling shutter (ERS) and global-release reset shutters
- **CSI1 serial interface:** The CSI1 receiver is compatible with the MIPI CSI1 specification. It supports the following features:
  - Image from sensor
    - Transfer of pixels and data received by the CSI1 DSI\_PHY RX to system memory or to the video pipeline
    - Unidirectional data link
    - 1D and 2D addressing mode
    - False synchronization code protection
    - Ping-pong mechanism for double-buffering
    - Support of RGB, RAW, YUV, and JPEG formats
  - Image read from memory
    - RAW formats supported
- **MIPI CSI2 serial interface:** The camera ISP supports one MIPI CSI2 serial interface (CSIa) with 2 data lanes. MIPI CSI2 enables data transfer at up to 1.6G bps. It is based on the MIPI CSI2 Specification 1.0.
  - Transfer pixels and data received by the CSI2 DSI\_PHY RX to the system memory or to the image pipeline
  - Uses unidirectional data link
  - Supports two data-configurable links, in addition to the clock signaling.
  - Maximum data rate of up to 800M bps per data lane
  - Data merger for two-data-lane configuration
  - Error detection and correction by the protocol engine
  - DMA engine integrated with dedicated FIFO
  - 1-D and 2-D addressing mode (rotation is not supported by the 2D mode)
  - Ping-pong mechanism for double buffering
  - Burst support
  - JPEG support for unknown length transfer
  - RGB, RAW, and YUV formats supported
  - Storage in progressive mode for interlaced stream (using line numbering)
  - Conversion of the RGB formats
- **Parallel interface:** The camera parallel interface (CPI) supports two modes:
  - **SYNC mode:** In this mode, the image-sensor module provides horizontal and vertical synchronization signals to the parallel interface, along with the pixel clock. This mode works with 8-, 10-, 11-, and 12-bit data (above 10-bit RAW data, the processing pipe cannot be used; data must be transferred to memory). SYNC mode supports progressive and interlaced image-sensor modules.
  - **ITU mode:** In this mode, the image-sensor module provides an ITU-R BT 656-compatible data

stream. The horizontal and vertical synchronization signals are not provided to the interface. Instead, the data stream embeds start-of-active (SAV) and end-of-active video (EAV) synchronization code. This mode works in 8- and 10-bit configurations.

---

**NOTE:**

- Up to 8-bit data at 130 MHz can be transferred to memory.
  - Up to 10-bit data at 75 MHz can be processed by the image pipeline or transferred to memory.
  - Up to 12-bit data at 75 MHz can be transferred to memory as is, or after processing inside the CCDC. It can also be internally converted to 10-bit data for full processing.
- 

The parallel interface can be active simultaneously with one serial interface (only CSIa). However, the serial interface cannot use the video-processing hardware when the parallel interface is active. The parallel interface can use the video-processing hardware.

---

**NOTE:** CPI and CSIb cannot be active at the same time, due to a pin-muxing limitation.

---

- **Video processing:** The video-processing hardware removes the need for expensive camera modules to perform processing functions. The hardware pipeline contains two parts: front end and back end.
    - **Video processing front end (VPFE):** Performs signal-processing operations on RAW image input data. The output data can go directly to memory for software processing, or to the video-processing back end for further processing. The video-processing front end is supported by the CCDC module. Signal-processing operations include:
      - Optical clamping
      - Optical black clamp
      - Black-level compensation
      - Look-up table (LUT) based faulty pixel correction
      - 2D lens-shading compensation
      - Data formatter
      - Output formatter
- 

**NOTE:** Up to 12-bit data at 83 MHz can be transferred from the video port to the ISP submodules. The video processing ISP can treat 1 pixel every two interconnect clock cycles.

---

- **Video processing back end (VPBE):** Performs signal-processing operations on RAW image input data. Outputs YCbCr 4:2:2 data.
  - **Preview module:** Signal-processing operations include:
    - A-law decompression: transforms non-linear 8-bit data to 10-bit linear data. The CCDC module can perform A-law compression
    - Noise reduction and faulty pixel correction
      - Dark frame capture and subtraction
      - Horizontal median filter
      - Programmable filter: 3x3 kernel of the same color
      - Couplet faulty pixel correction
    - Digital gain
    - White balance
    - Programmable color filter array (CFA) interpolation: 5x5 kernel
    - Black adjustment
    - Programmable color correction (RGB to RGB)
    - Programmable gamma correction: 1024 entries for each color

- Programmable color conversion (RGB to YCbCr 4:4:4)
- Color subsampling (YCbCr 4:4:4 to YCbCr 4:2:2)
- Luminance enhancement (non-linear), chrominance suppression and offset

The preview module can also work from memory to memory.

- **Resizer module:** Performs on-the-fly upsampling (up to x4) and downsampling (down to x0.25) of YCbCr 4:2:2 data by applying high-quality horizontal and vertical filters. The horizontal and vertical resizer ratios are independent. Applicable ratios are 256/N, with N ranging from 64 to 1024. This feature enables digital zooming (upsampling) and video preview (downsampling).

The resizer module can also work from memory to memory. Higher or lower ratios can be obtained by combining on-the-fly resizing followed by memory-to-memory resizing.

- **Statistic collection modules (SCM):** The host CPU uses statistics to adjust various parameters for processing image data.
  - **3A metrics:** Collects on-the-fly RAW image data metrics, which are required to perform the control loops for auto white balance (AWB), auto exposure (AE), and autofocus (AF). The MPU subsystem typically uses data metrics to adjust various parameters for processing image data.
  - **Histogram:** Performs on-the-fly pixel binning of RAW image, based on color value ranges and regions. Supports up to 4 regions and up to 256 bins per color. The MPU subsystem typically uses the histogram with 3A metrics to adjust various parameters for processing image data.

The histogram module can also work from memory to memory.

- **Central-resource shared buffer logic (SBL):** Buffers and schedules memory accesses requested by camera ISP modules
- **Circular buffer:** Prevents storage of full image frames in memory when data must be postprocessed and/or preprocessed by software
- **Memory management unit (MMU):** Manages virtual-to-physical address translation for external addresses and solves the memory-fragmentation issue. Enables the camera driver to dynamically allocate and deallocate memory; the MMU handles memory fragmentation.
- **Clock generator:** Generates two independent clocks that can be used by two external image sensors
- **Timing control:**
  - Generation of two clocks that can be used by the external image sensors
  - Generation of signals for strobe flash, mechanical shutter, and global reset. Support for red-eye removal.
- **Open core protocol (OCP) compliant:**
  - One 64-bit master interface connected to L3
  - One 32-bit slave interface connected to L4

## 12.2 Camera ISP Environment

### 12.2.1 Camera ISP Functions

Table 12-1 describes the camera ISP functions and the corresponding application fields.

**Table 12-1. Camera ISP Functions**

Function	Description
Parallel interface in generic configuration (SYNC mode)	The camera ISP supports up to 12 bits (Most image-processing pipeline operations support only up to 10 bits; when it is more than 10 bits, some limited capabilities apply to CCDC only). The camera ISP can interface with RAW interlaced or progressive image sensors using RGB or complementary color mosaic filters.
Parallel interface in ITU-R BT.656 configuration (ITU mode)	The camera ISP can extract the synchronization signal start of active video and end of active video from the ITU-R BT.656 bit stream. 8-bit and 10-bit modes are supported.
CS1b serial interface configuration (serial mode) (CSI1)	The camera ISP supports one CSI1 (CSI1b).
CS1a serial interface configuration (serial mode) (MIPI CSI2)	The camera ISP supports one MIPI CSI2 serial interface (CS1a).

**NOTE:** The CS1a (CSI2 receiver) and CS1b (CSI1 receiver) can be active simultaneously. The CS1a or CS1b interface data can go through the video-processing hardware. The CSI interface not using the video-processing hardware goes directly to memory.

The parallel interface is limited to 10 bits when used simultaneously with CS1a (CSI2 receiver).

The parallel interface cannot be used simultaneously with CS1b (CSI1 receiver).

### 12.2.2 Camera ISP Signal Descriptions

**Table 12-2. I/O Description**

Signal Name	I/O <sup>(1)</sup>	Description	Parallel SYNC Mode	Parallel ITU Mode	Serial Mode CSI1	Serial Mode CSI2

**NOTE:** For more information about initializing and configuring the signals along with the complex I/Os, see [Section 12.5.1, Programming the CSI1 or CSI2 Receiver Associated Complex I/O](#).

### 12.2.3 Camera ISP Modes

- **Parallel interface in generic configuration**

[Figure 12-2](#) shows a block diagram of the parallel interface in generic configuration.

Figure 12-2. Parallel Interface in Generic Configuration

camisp-002

- (1) There is no mux control bit. If the CSib interface is enabled, the cam\_d6 to cam\_d9 pins are used by the CSib interface.
- (2) These signals are muxed. They are controlled by the CONTROL\_PADCONF\_CAM\_FLD and CONTROL\_PADCONF\_CAM\_D1 registers.

**CAUTION**

The parallel interface in generic configuration mode works with 8-, 10-, 11-, and 12-bit sensors. 8 to 12 bits refers to data-lane count, not pixel coding. For example, when a video decoder is used, it sends 16 bits per pixel. The data is transmitted through 8 data lanes at x2 pixel clock. The bridge can be used to reassemble the 16-bit pixels.

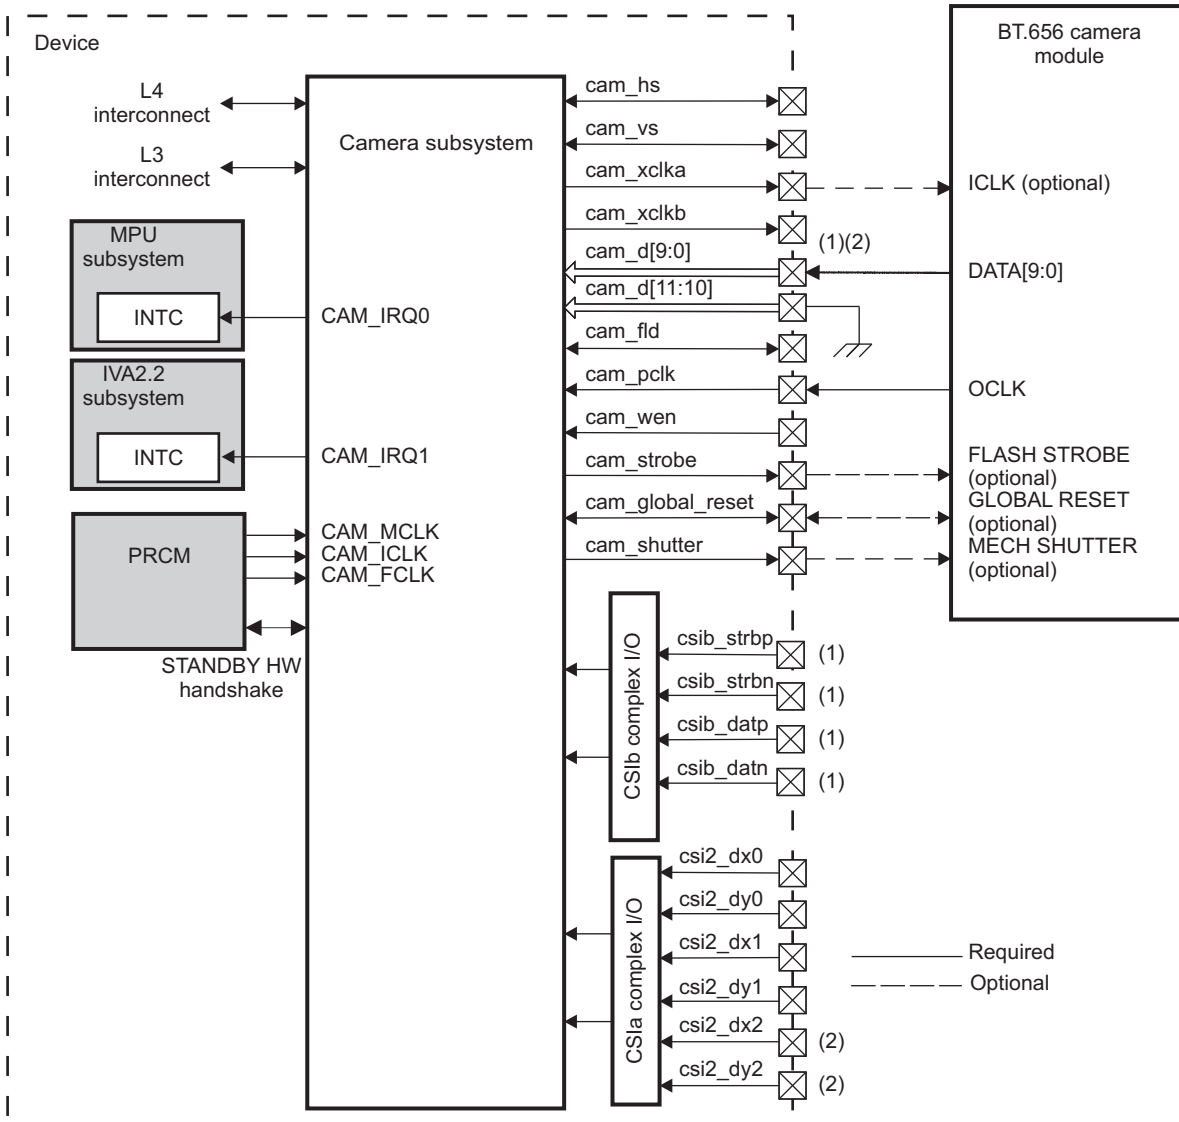

**NOTE:** For information about using the data-lane shifter for different configurations, see [Table 12-27](#).

**NOTE:** Due to a pin-muxing limitation, CPI and CS1b cannot be active at the same time.

• **Parallel interface in ITU-R BT.656 configuration**

Figure 12-3 is a block diagram of the parallel interface in ITU-R BT.656 configuration.

**Figure 12-3. Parallel Interface in ITU-R BT.656 Configuration**

camisp-003

- (1) There is no mux control bit. If the CS1b interface is enabled, the cam\_d6 to cam\_d9 pins are used by the CS1b interface.
- (2) These signals are muxed. They are controlled by the CONTROL\_PADCONF\_CAM\_FLD and CONTROL\_PADCONF\_CAM\_D1 registers.

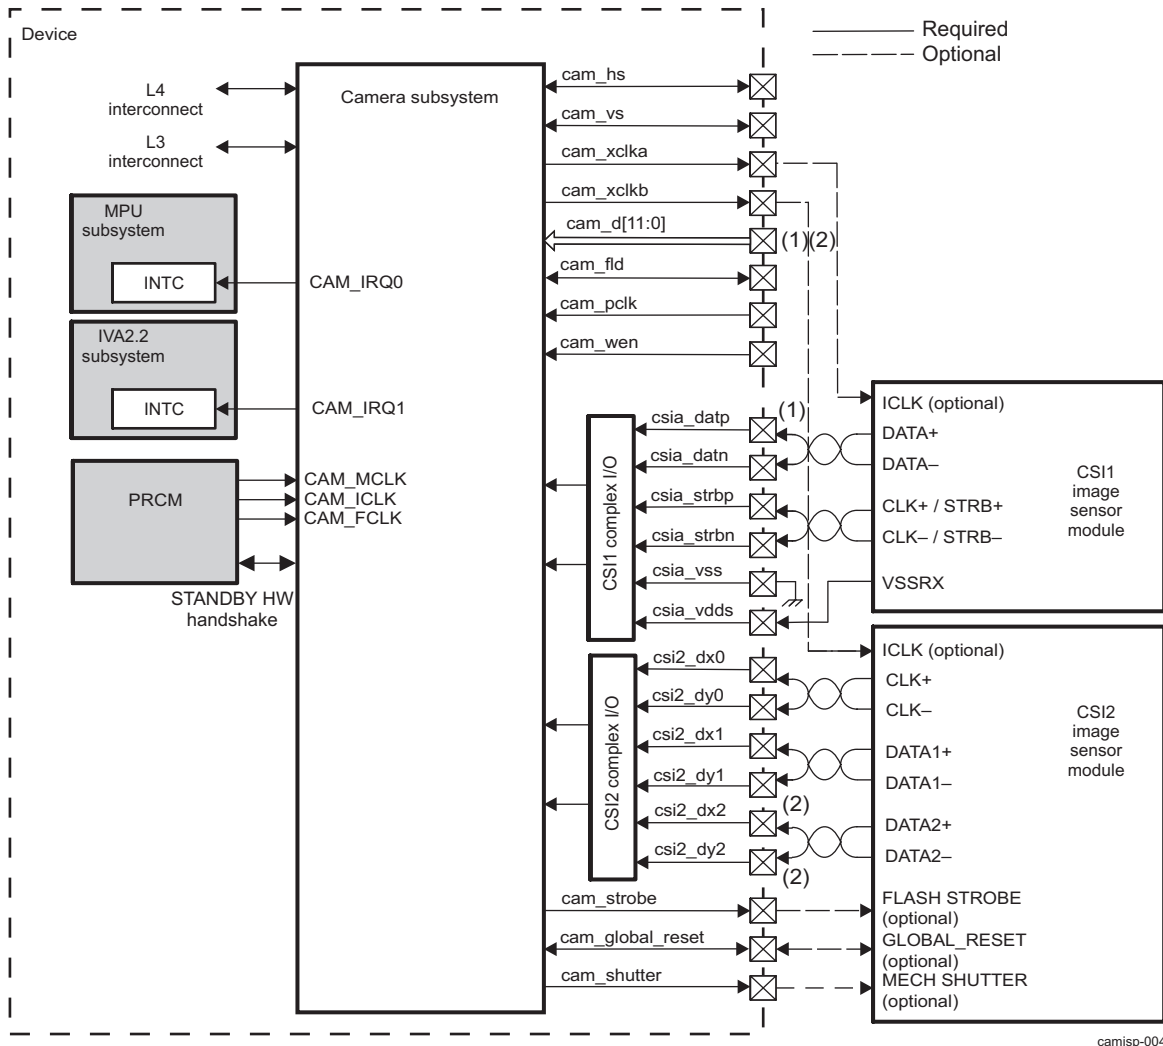

**NOTE:** For information about using the data-lane shifter for different configurations, see [Table 12-27](#).

**NOTE:** A pin-muxing limitation prevents CPI and CS1b from being active at the same time.

• **Serial interface configuration**

Figure 12-4 shows a block diagram of the serial interface configuration.

Figure 12-4. CSI2, CSI1 Serial Interface Configuration

- (1) There is no mux control bit. If the CS1b interface is enabled, the cam\_d6 to cam\_d9 pins are used by the CS1b interface.
- (2) These signals are muxed. They are controlled by the CONTROL\_PADCONF\_CAM\_FLD and CONTROL\_PADCONF\_CAM\_D1 registers.

**NOTE:** Due to a pin-muxing limitation, CPI and CS1b cannot be active at the same time.

cam\_strobe, cam\_global\_reset, and cam\_shutter can be connected to the CSI1 camera module instead of CSI2 camera module.

camisp-004

## 12.2.4 Camera ISP Protocols and Data Formats

### 12.2.4.1 Parallel Generic Configuration Protocol and Data Format (8, 10, 11, 12 Bits)

The SYNC mode implements a generic parallel interface with the image sensor. The SYNC mode supports 8 to 14-bit-wide data signals.

In this configuration, no assumptions are made on the data format of pixels, but the dynamic range is limited to 8-, 10-, 12- or 14-bit (data can be pure luminance for black and white sensor, RGB444, Bayer RGB, etc.). The pixel data is presented on cam\_d, where one pixel is sampled for every cam\_pclk rising edge (or falling edge, depending on the configuration of cam\_pclk polarity). For more information, see [Section 12.4](#).

Additional pixel times between rows represent blanking periods. Active pixels are identified by a combination of two additional timing signals: horizontal synchronization (cam\_hs) and vertical synchronization (cam\_vs). During the image-sensor readout, these signals define when a row of valid data begins and ends, and when a frame starts and ends.

**NOTE:** For correct operation, the clock cam\_pclk must run during blanking periods (cam\_hs and cam\_vs inactive). cam\_pclk must start before sending cam\_d and start cam\_vs and cam\_hs.

[Figure 12-5](#) and [Figure 12-6](#) show the frame and data timing, respectively, based on synchronization signals in the parallel No BT configuration.

**Figure 12-5. Synchronization Signals and Frame Timing in SYNC Mode**

**Figure 12-6. Synchronization Signals and Data Timing in SYNC Mode**

**NOTE:** The pixel clock can be gated to qualify valid pixels. It can also be gated during blanking periods to reduce power consumption. However, at least 4 clock pulses are required before sending active image data and synchronization information; 8 clock pulses are required after the end of active video. Extra-clock pulses are allowed but not required during the line blanking periods.

[Figure 12-7](#) shows the timing diagram of the SYNC move clock gating.

Figure 12-7. SYNC Mode Clock Gating

108-132

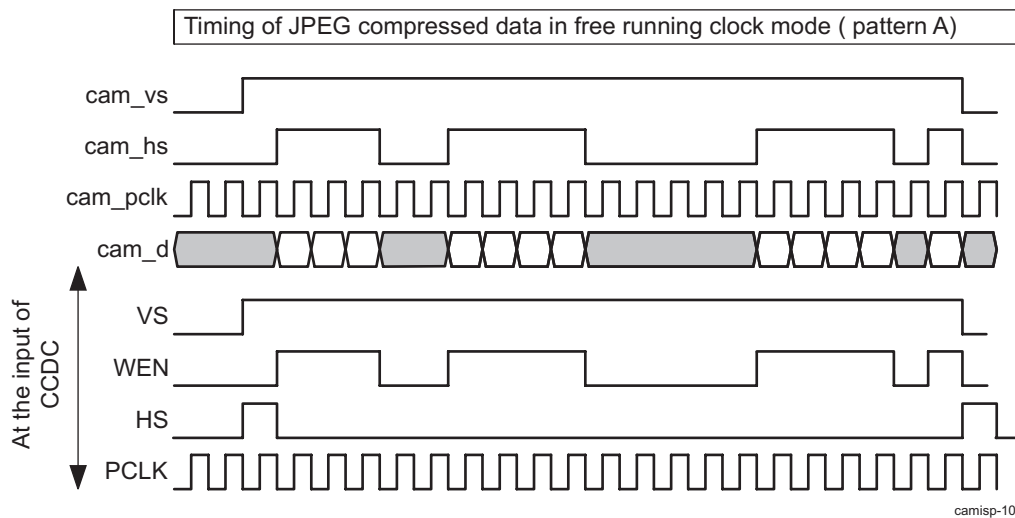

12.2.4.2 Parallel Generic Configuration: JPEG Sensor Connection on the Parallel Interface

Some camera modules integrate an image-signal processor (ISP) and a JPEG encoder. The CCDC can interface with these camera modules and transfer the received JPEG stream to memory.

Only pattern A mode is supported. To use this mode, set the `ISP_CTRL [30] JPEG_FLUSH` bit.

Figure 12-8 shows timing diagrams for an A pattern.

Figure 12-8. JPEG Stream Timing Diagrams

**CAUTION**  
The bridge cannot be used for JPEG sensor connections.

12.2.4.3 ITU-R BT.656 Protocol and Data Format (8, 10 Bits)

**CAUTION**  
The ITU-R BT.656 mode cannot be used when the bridge is enabled.

The camera ISP interface supports data in ITU-R BT.656 format.

The ITU-R BT.656 standard specifies a method of transferring YUV422 data over an 8- or 10-bit video interface.

Figure 12-9 shows the data timing diagram with embedded synchronization signal.

**Figure 12-9. Data Timing With Embedded Synchronization Signals (8-Bit Case)**

In BT.656, the data words (8- or 10-bit) in which the eight most-significant bits (MSBs) are all set to 1, or all set to 0 are reserved. Only 254 of the possible 256 8-bit word values, and 1016 of the possible 1024 10-bit word values represent signal values.

The data is multiplexed in the following order: Cb0 Y0 Cr0 Y1 Cb2 Y2 Cr2 Y3, etc., where the byte sequence Cb2n Y2n Cr2n refers to interleaved luminance and chroma samples and the following byte Y2n + 1 corresponds to the next luminance sample.

The BT.656 protocol uses unique timing reference signals embedded in the video stream. The synchronization signals cam\_hs and cam\_vs are not needed. This reduces the number of wires required for a BT.656 video interface.

There are two timing reference codes: The start of active video (SAV) reference code precedes each video data block, and the end of active video (EAV) follows each video block. Each timing reference signal consists of a 4-byte sequence in the following hexadecimal format: **FF 00 00 XY**. The first 3 bytes are a fixed preamble (See the ITU-R BT.656 specification). The fourth byte (XY) contains information defining field identification (F), blanking (V), and SAV/EAV information (H), and 4 parity bits calculated as a function of F, V, and H (see the ITU-R BT.656 specification).

Table 12-3 lists the video timing reference codes for SAV and EAV.

**Table 12-3. Video Timing Reference Codes for SAV and EAV**

Data Bit Number	First Word (FF)	Second Word (00)	Third Word (00)	Fourth Word (XY)
9 (MSB)	1	0	0	1
8	1	0	0	F
7	1	0	0	V
6	1	0	0	H
5	1	0	0	P3
4	1	0	0	P2
3	1	0	0	P1
2	1	0	0	P0
1	1	0	0	0
0	1	0	0	0

Table 12-4 contains a description of the F, V, and H signals.

**Table 12-4. F, V, H Signal Descriptions**

Signal	Value	Command
F	0	Field 1
	1	Field 2
V	0	0
	1	Vertical blank
H	0	SAV
	1	EAV

The resulting Hamming distance between any two code words is four, allowing two error detections and one error correction. To enable or disable the error-correcting capability, configure the [CCDC\\_REC656IF \[1\] ECCFVH](#) bit.

---

**NOTE:** The 2-bit errors are detected, but not flagged or corrected. Errors of more than 2 bits are not corrected or flagged.

---

[Table 12-5](#) lists the F, V, and H protection (error-correction) bits.

**Table 12-5. F, V, H Protection (Error-Correction) Bits**

F	V	H	P3	P2	P1	P0
0	0	0	0	0	0	0
0	0	1	1	1	0	1
0	1	0	1	0	1	1
0	1	1	0	1	1	0
1	0	0	0	1	1	1
1	0	1	1	0	1	0
1	1	0	1	1	0	0
1	1	1	0	0	0	1

When operating in CCIR-656 mode, data is stored in SDRAM according to the format shown in [Table 12-6](#) when [CCDC\\_SYN\\_MODE \[11\] PACK8](#) is enabled.

**Table 12-6. BT.656 Mode Data Format in SDRAM**

8 bit x 4	Pixel3 (Y1/Cr0)	Pixel2 (Cr0/Y1)	Pixel1 (Y0/Cb0)	Pixel0 (Cb0/Y0)
	Bit 31			Bit 0

---

**NOTE:** The CCDC outputs the XY code in the SAV and EAV into memory. To eliminate this, users must set the SPH register field to +1. In addition, the NPH register field must be set to accurately represent the number of active pixels.

---

#### 12.2.4.4 Camera Serial Interface (CSI1) Protocol and Data Formats

This section describes CSI1 protocol and data formats. [Table 12-7](#) describes the I/O for serial interface CSI1.

**Table 12-7. I/O Description for Serial Interface CSI1**

Signal Name		I/O <sup>(1)</sup>	Description	Value at Reset
csib_datp	CAM_S_DATA	I	Serial data input	N/A
csib_datn				
csib_strbp	CAM_S_CLK	I	Serial clock input	N/A
csib_strbn				

<sup>(1)</sup> I = Input, O = Output

From the device point of view, the CSI1 interface comprises four differential inputs representing two effective signals: the serial data and the clock.

From the camera ISP side, the CSI1 interface comprises two serial inputs (CAM\_S\_DATA and CAM\_S\_CLK) that are the result of low-voltage differential signal (LVDS) converters, as shown in [Figure 12-10](#).

[Figure 12-10](#) shows all possible interfaces of the camera ISP in the CSI1 serial configuration.

**NOTE:** For more information about initializing and configuring the signals along with the complex I/Os, see [Section 12.5.1, Programming the CSI1 or CSI2 Receiver Associated Complex I/O.](#)

**Figure 12-10. CSI1 Receiver Configuration Interface Signals**

camisp-180

**NOTE:** The complex I/O between the CSI1 receiver and an external camera can be configured to transfer data in serial or in parallel mode. The scheme in [Figure 12-10](#) represents the serial setting: CSI1\_CTRL [2] IO\_OUT\_SEL = 0x0. This bit must be set to 0x1 to transfer data at the output of the complex I/O in parallel. See [Section 12.4.2.2.2, Complex I/O](#), for details.

The CSI1 receiver is a serial interface to an image sensor. Signals from the camera are a serial input data (CAM\_S\_DATA) and a clock signal (CAM\_S\_CLK).

Each frame is clearly identified by four unique 32-bit synchronization codes: frame start, frame end, line start, and line end, which are embedded in the serial bitstream. The logical channel identification number is also encoded in the synchronization codes.

- Frame-start code (FSC): Identifies the start of a new frame
- Line-start code (LSC): Identifies the start of a new line and is received for every line, except the first line, that starts with an FSC
- Line-end code (LEC): Identifies the end of a line and is received for every line, except the last line, that ends with an FEC
- Frame-end code (FEC): Identifies the end of the last line and the end of the current frame

[Table 12-8](#) summarizes the 32-bit synchronization code values.

**Table 12-8. Synchronization Codes**

Synchronization Code	Value	Comments
LSC	0xFF00 0000	Aligned on a 32-bit boundary Not used in case of JPEG8 data
LEC	0xFF00 0001	Aligned on a 32-bit boundary Not used in case of JPEG8 data
FSC	0xFF00 0002	Aligned on a 32-bit boundary
FEC	0xFF00 0003	Aligned on a 32-bit boundary

The CSI1 receiver interface has several image-data operating modes, summarized in [Table 12-9](#).

**Table 12-9. CSI1 Image Data Operating Modes and Alignment Constraints**

CSI1_CTRL 1[7:3] Format	CSI1 Data Format	OCF Bits per Pixel (bpp) (when sending data to memory, N/A when sending to VP)	Width Constraint: Must Be a Multiple of n Pixels	Storage Increase Versus Packed	2D Mode Availability <sup>(1)</sup>	Comments
0x0	YUV422 big endian	16	8	N/A	Yes	
0x1	YUV422 little endian	16	8	N/A	Yes

0x18	RAW12	12	32	N/A	No	

<sup>(1)</sup> If 2D mode is available; there are no supplementary constraints on data width. 2D mode is not applicable when sending to video port (VP).

The CSI1 receiver can cope with all data formats if the data line length sent through the CS1 physical protocol is a multiple of 32 bits. This condition is required for the CSI1 receiver to work correctly.

However, some data formats impose stronger line-length constraints to correctly finish pixel reconstruction at the end of the lines. If the additional constraints are not respected:

- Only the last reconstructed pixels in every line are erroneous. The missing bits are replaced with 0s to perform pixel reconstruction.
- The FW\_IRQ interrupt is triggered.

### 12.2.4.4.1.1 YUV CSI1 Operating Modes

The YUV422 data format can be stored to memory in little- or big-endian format. The line length sent through the CSI1 physical protocol must be a multiple of 32 bits.

YUV422 data format can also be sent to the video port.

YUV422 + VP is used to output RAW8 data to the video port: YUV422 + VP is equivalent to RAW8 + VP. Figure 12-12 and Figure 12-13 show big-endian and little-endian YUV422 format, respectively.

**Figure 12-12. YUV422 Big Endian**

camisp-181

Figure 12-13. YUV422 Little Endian

YUV422 little endian

Transmitter

Receiver

First two pixels of first odd line are:  $\{y_1, v_1, u_1\}$  and  $\{y_2, v_1, u_1\}$   
 First two pixels of first even line are:  $\{y_{n+1}, v_{n+1}, u_{n+1}\}$  and  $\{y_{n+2}, v_{n+1}, u_{n+1}\}$

- t0: VP\_DATA[7:0] = [u7 u6 u5 u4 u3 u2 u1 u0]
- t1: VP\_DATA[7:0] = [y7 y6 y5 y4 y3 y2 y1 y0]
- t2: VP\_DATA[7:0] = [v7 v6 v5 v4 v3 v2 v1 v0]
- t3: VP\_DATA[7:0] = [y7 y6 y5 y4 y3 y2 y1 y0]

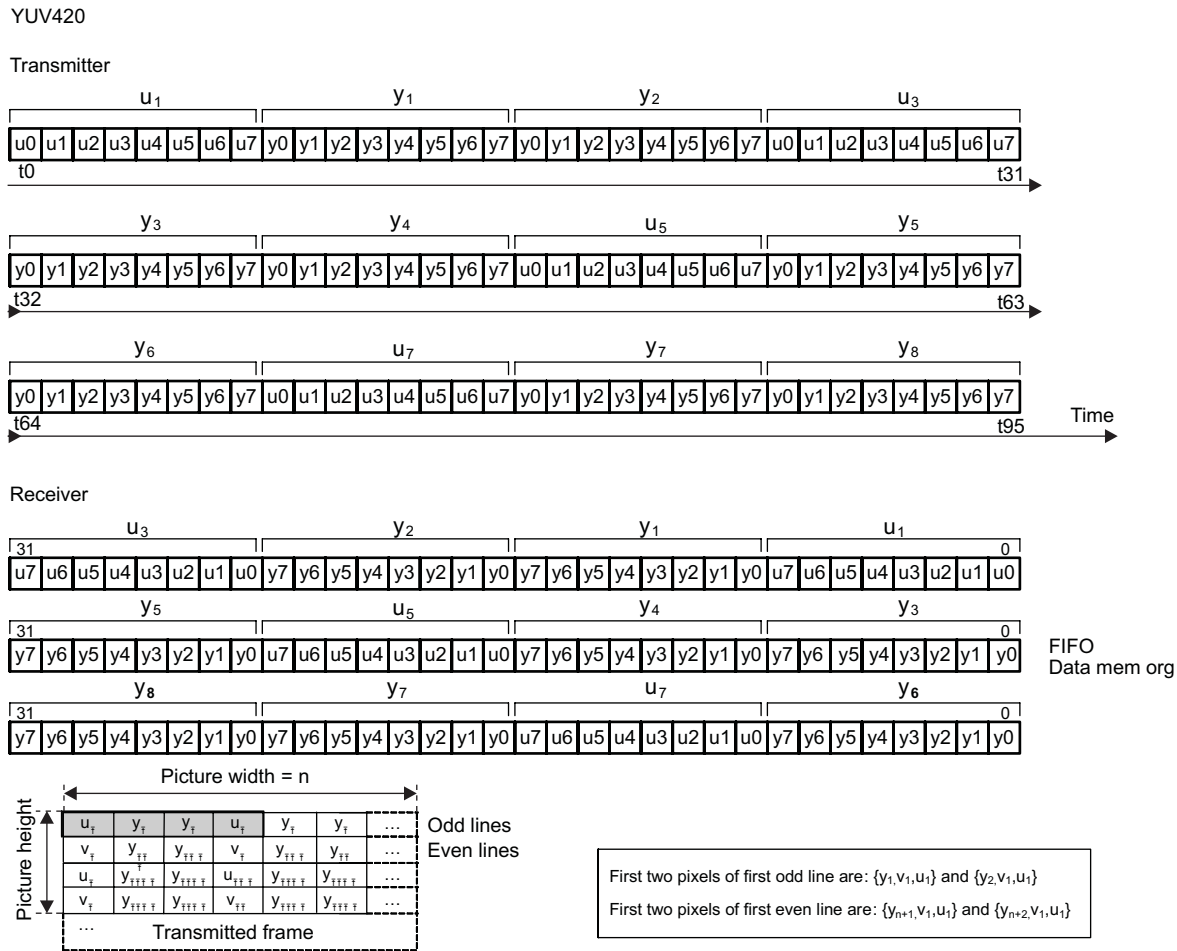

YUV4:2:2 + VP

camisp-182

The line length sent through the CSI1 physical protocol is a multiple of 32 bits. Furthermore, the line length is a multiple of 3 x 32 bits and the number of lines is even to correctly finish the pixel reconstruction.

The line structure is different for odd and even lines. Odd lines transport the U component, while even lines contain the V component. This is shown in [Figure 12-14](#).

Figure 12-14. YUV420

camisp-183

### 12.2.4.4.1.2 RGB CSI1 Operating Modes

RGB888 data format can be output to memory in two formats: with no data expansion and with data expansion.

If data expansion is used, the value of the 8 upper bits is programmable and can be set with an alpha value for computer graphics applications. The line length sent through the CSI1 physical protocol is a multiple of 32 bits. Furthermore, the line length is a multiple of 3 x 32 bits to correctly finish pixel reconstruction.

Figure 12-15 shows an example of RGB888 format.

Figure 12-15. RGB888

camisp-012

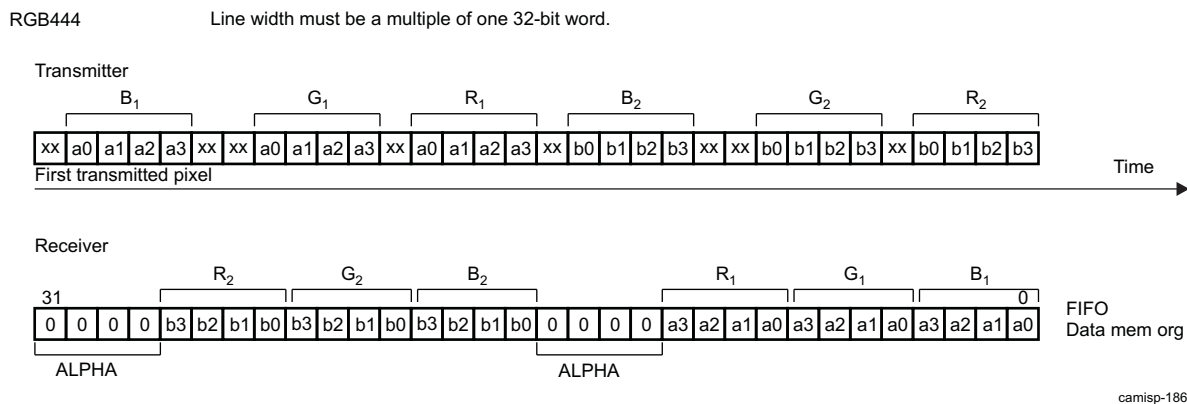

For RGB565, the line length sent through the CSI1 physical layer is a multiple of 32 bits (see Figure 12-16).

**Figure 12-16. RGB565**

RGB444 data format is output to memory with data expansion. If data expansion is used, the value of the 4 upper bits is programmable and can be set with an alpha value for computer graphics applications. The line length sent through the CSI1 physical layer is a multiple of 32 bits (see [Figure 12-17](#)).

**Figure 12-17. RGB444**

### 12.2.4.4.1.3 RAW Bayer RGB CSI1 Operating Modes

#### 12.2.4.4.1.3.1 RAW8

RAW8 data format can be output to memory in two formats: with no data expansion and with data expansion.

The line length sent through the CSI1 physical layer is a multiple of 32 bits.

[Figure 12-18](#) shows RAW8 format.

**NOTE:**

- Use YUV422 + VP to output RAW8 data to the video port: YUV422 + VP is equivalent to RAW8 + VP.

**Figure 12-18. RAW8**

t0: VP\_DATA[9:0] = [a7 a6 a5 a4 a3 a2 a1 a0]  
 t1: VP\_DATA[9:0] = [b7 b6 b5 b4 b3 b2 b1 b0]  
 t2: VP\_DATA[9:0] = [c7 c6 c5 c4 c3 c2 c1 c0]  
 t3: VP\_DATA[9:0] = [d7 d6 d5 d4 d3 d2 d1 d0]

RAW8 + VP

camisp-189

#### 12.2.4.4.1.3.2 RAW10

RAW10 data format can be output to memory in two formats: with no data expansion and with data expansion.

If data expansion is used, the 10-bit data are padded with 0s on a 16-bit word.

The line length sent through the CSI1 physical layer is a multiple of 32 bits. Furthermore, the line length is a multiple of 5 x 32 bits to correctly finish pixel reconstruction (the lowest common multiple of 32 and 10 is 320: 10 x 32 bits).

RAW10 data format can be sent to the video port.

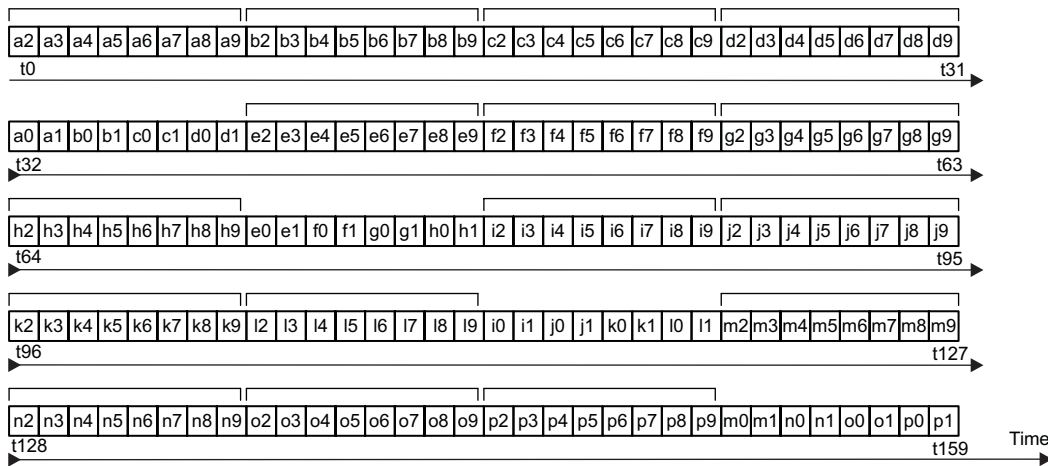

Figure 12-19 shows RAW10 format.

Figure 12-19. RAW10

RAW10 Line width must be a multiple of five 32-bit words.

Transmitter

t3: VP\_DATA[9:0] = [d9 d8 d7 d6 d5 d4 d3 d2 d1 d0]

RAW10 + VP

camisp-190

### 12.2.4.4.1.3.3 RAW12

RAW12 data format can be output to memory in two formats: with no data expansion and with data expansion.

If data expansion is used, the 12-bit data are padded with 0s on a 16-bit word.

The line length sent through the CSI1 physical layer is a multiple of 32 bits. Furthermore, the line length is a multiple of 3 x 32 bits to correctly finish pixel reconstruction (the lowest common multiple of 32 and 12 is 96: 3 x 32 bits).

RAW12 data format can be sent to the video port.

Figure 12-20 shows RAW12 format.

**NOTE:** The hardware pipe is 10-bit only. Typically, the data lane shifter must be used to perform 10-bit-only processing.

Figure 12-20. RAW12

### 12.2.4.4.1.4 JPEG8 CS11 Operating Modes

The line length sent through the CS11 physical layer is a multiple of 32 bits. The false synchronization protection (FSP) code insertion on the transmitter side automatically ensures this line length. It is impossible to know in advance the size of a compressed stream. Figure 12-21 shows JPEG8 and JPEG8 FSP format.

**Figure 12-21. JPEG8 and JPEG8 FSP**

In JPEG8 mode, the JPEG encoder on the sensor side must avoid generating data equal to the synchronization code and must deliver a synchronization-code-free bitstream.

In JPEG8 FSP mode, the bitstream is a standard JPEG8 bitstream in which byte-stuffing is used to differentiate synchronization code from original data with the same value. Thus, the JPEG encoder can generate a standard bitstream, and a postprocessing stage (FSP encoder) is used to highlight natural bitstream data equal to synchronization codes, so that the other end can discard the false synchronization codes.

FSP decoding is performed for byte-aligned data and occurs after the frame-start synchronization code is received. If the byte  $n = 0x0$ , the FSP decoder looks for bytes 1 and 2. If the bytes are equal to an illegal combination (synchronization codes), the byte  $0xA5$  that comes after (byte  $n + 1$ ) is removed from the bitstream.

The  $0xA5$  padding bytes at the end of the frame are also removed by FSP decoding so that padding does not generate additional data in the FIFO. FSP decoding is then transparent to the software.

Normally, the module detects the illegal combination and then the  $0xA5$ . When the  $0xA5$  is corrupted or replaced by another code, the value is automatically removed from the bitstream and an interrupt is generated to signal that the code is corrupt and therefore the received data are suspicious. If the line is too noisy for FSP decoding, it is better to configure the subsystem in JPEG8 and use software postprocessing.

### 12.2.4.5 Camera Serial Interface (CSI2) Protocol and Data Format

The CSI2 supports MIPI CSI2. This section describes MIPI CSI2 protocol and data formats.

#### 12.2.4.5.1 Physical Layer

Table 12-10 lists the CSI2 receiver I/O.

**Table 12-10. I/O Description for CSI2 Serial Interface**

Signal Name		I/O <sup>(1)</sup>	Description	Value at Reset
csi2_dx0	line 1	I	Serial data/clock input	N/A
csi2_dy0				
csi2_dx1	line 2	I	Serial data/clock input	N/A
csi2_dy1				
csi2_dx2	line 3	I	Serial data/clock input	N/A
csi2_dy2				

<sup>(1)</sup> I = Input

**NOTE:** Each serial line (line 1, line 2, and line 3) can be used as clock lane or data lane. The MIPI CSI2 protocol requires one clock line (others are data lane or unused lane).

From the device point of view, the CSI2 interface comprises six differential input signals representing three lanes: the serial clock and one or two serial data.

Lanes support four operating modes:

- HS mode: High-speed transmit mode
- LP mode: Low-power transmit mode
- ULPM: Ultra-low power mode used between two transmissions
- Off mode: Lane is off.

### 12.2.4.5.2 Lane Merger

The layer consists of lane merger logic to merge the incoming serial stream into a byte stream. The bits are sent with the LSB first. The order of the lanes at the CSI2 receiver core depends on the lane configuration.

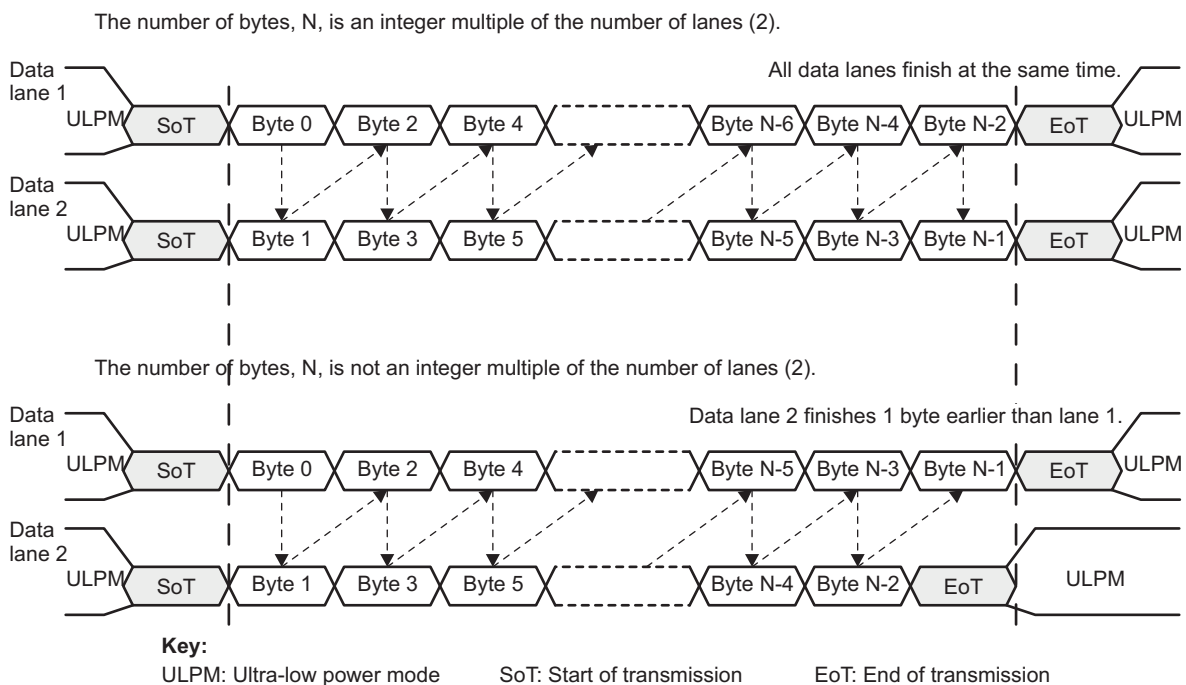

The number of lanes and their configuration can be changed only in ULPM or when all data lanes are in off mode.

The lane merger can merge two lanes into a single byte stream.

In case of a single lane, the lane merger is not used to merge byte streams.

Figure 12-22 and Figure 12-23 show the byte position into each serial link for 1 and 2 data lane configurations. The byte stream always starts from lane 1. It finishes on one of the lanes, depending on the number of bytes to receive and the number of lanes.

**Figure 12-22. Two Data-Lane Merger Configuration**

camisp-239

**Figure 12-23. One Data-Lane Configuration**

camisp-240

### 12.2.4.5.3 Protocol Layer

The low-level protocol (LLP) is a byte-oriented protocol from the lane merger layer. It supports short and long packet formats.

The CSI2 protocol layer defines how image-sensor data is transported onto the physical layer.

The feature set of the protocol layer implemented by the CSI2 receiver is:

- Transport of arbitrary data (payload-independent)
- 8-bit word size
- Support for up to four interleaved virtual channels on the same link
- Special packets for frame-start, frame-end, line-start, and line-end information
- Descriptor for the type, pixel depth, and format of application-specific payload data
- Error-correction code (ECC) for 1-bit error correction or 2-bit error detection in the header
- 16-bit checksum code for payload error detection

Figure 12-24 shows the CSI2 protocol layer with short and long packets.

**Figure 12-24. CSI2 Protocol Layer With Short and Long Packets**

camisp-241

Two packets are always separated from each other with a sequence of a ULPM, an ET, and an ST.

#### 12.2.4.5.3.1 Short Packet

A short packet is identified by data types 0x00 to 0x0F. A short packet can be used for frame or line synchronization or for generic data. Figure 12-25 shows the structure of a short packet.

**Figure 12-25. Short Packet Structure**

camisp-242

For frame-synchronization data types, the short packet data field is the frame number. For line-synchronization data types, the short packet data field is the line number. For generic short packet data types, the content of the short packet data field is user-defined.

The 16-bit frame number, when used, is always nonzero to distinguish it from the use case where the frame number is inoperative and remains set to 0. The behavior of the 16-bit frame number is one of the following:

- The frame number is always 0. The frame number is inoperative.
- The frame number increments by 1 for every FS packet with the same virtual channel and is periodically reset to 1 (1, 2, 1, 2, 1, 2, 1, 2 or 1, 2, 3, 4, 1, 2, 3, 4).

For line-start code (LSC) and line-end code (LEC) synchronization packets, the short packet data field contains a 16-bit line number. This line number is the same for the LS and LE packets corresponding to a given line. Line numbers are logical line numbers and do not necessarily equal physical line numbers. The 16-bit line number, when used, is always nonzero to distinguish it from the case where the line number is inoperative and remains set to 0.

The behavior of the 16-bit line number is one of the following:

- The line number is always 0. The line number is inoperative.
- The line number increments by one for every LS packet within the same virtual channel and the same data type. The line number is periodically reset to 1 for the first LS packet after an FS packet. The intended usage is for progressive scan (non-interlaced) video data streams. The line number must be a nonzero value.
- The line number increments by the same arbitrary step value greater than one for every LS packet within the same virtual channel and the same data type. The line number is periodically reset to a nonzero arbitrary start value for the first LS packet after an FS packet. The arbitrary start value can be different between successive frames. The intended usage is for interlaced video data streams.

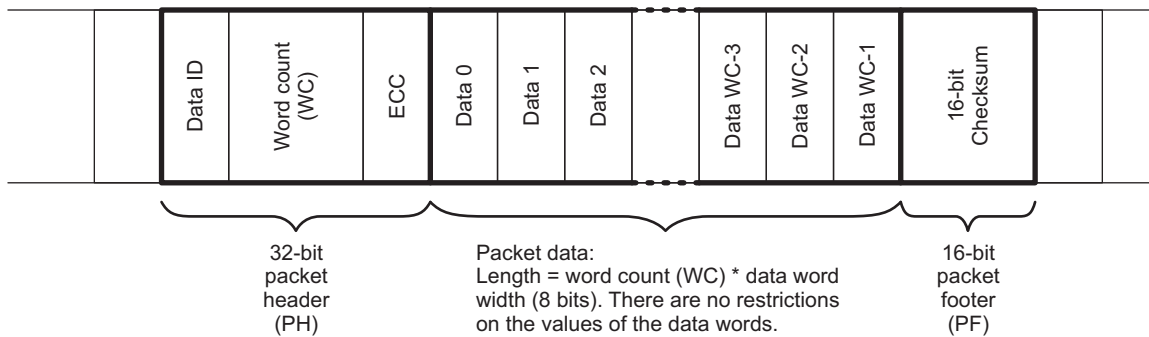

The ECC byte allows single-bit errors to be corrected and 2-bit errors to be detected in the short packet.

Short packets apply to all contexts using the same virtual channel ID (there are up to eight contexts to support eight dedicated configurations of virtual channel ID and data types). The data type associated with the context is not used to distinguish which context is used when receiving short packets.

### 12.2.4.5.3.2 Long Packet

A long packet is identified by data types 0x10 to 0x37. A long packet consists of three elements: a 32-bit packet header (PH), an application-specific data payload with a variable number of 8-bit data words, and a 16-bit packet footer (PF). The packet header is further composed of three elements: an 8-bit data identifier, a 16-bit word count field, and an 8-bit ECC. The packet footer has one element, a 16-bit checksum. [Figure 12-26](#) and [Table 12-11](#) show the structure of a long packet.

**Figure 12-26. Long Packet Structure**

camisp-243

**Table 12-11. Long Packet Structure Description**

Packet Part	Field Name	Size (Bit)	Description
Header	Data ID	8	Contains the virtual channel identifier and the data-type information
	Word count	16	Number of data words in the packet data. A word is 8 bits.
	ECC	8	ECC for data ID and WC field. Allows 1-bit error recovery and 2-bit error detection.
Data	Data	WC * 8	Application-specific payload (WC words of 8 bits)
Footer	Checksum	16	16-bit cyclic redundancy check (CRC) for packet data

There are no restrictions on packet data size, but each data format can impose additional restrictions on the length of the payload data (for example, a multiple of 4 bytes).

### 12.2.4.5.3.3 Data Identifier

The data identifier byte contains the virtual channel identifier (VC) value and the data-type (DT) value, as shown in Figure 12-27. The VC is in the 2 MSBs of the data identifier byte. The DT value is in the 6 LSBs of the data identifier byte.

Figure 12-27 shows the data identifier structure.

**Figure 12-27. Data Identifier Structure**

camisp-244

### Virtual Channel

The CSI2 protocol layer transports virtual channels. Virtual channels are built up of frames. A frame can comprise embedded data and image-sensor data. Two contexts are used to send the two types of data separately. Each frame is identified by unique mandatory synchronization codes: frame start and frame end. The following synchronization codes are optional for the transmitter: line start and line end. A set of registers is associated with each context defined by the virtual channel ID and the data type. Figure 12-28 shows a virtual channel.

Figure 12-28. Virtual Channel

**Pixel Formats**

Image-sensor data can have multiple data types. [Table 12-12](#) summarizes the pixel formats supported by the CSI2 receiver interface.

Table 12-12. CSI2 Pixel Format Modes

Mode	Description
YUV420 8-bit	YUV4:2:0 image data
YUV420 8-bit + VP	YUV4:2:0 image data
YUV420 10-bit	YUV4:2:0 image data
YUV420 8-bit legacy	YUV4:2:0 image data
YUV420 8-bit + CSPS	YUV4:2:0 image data
YUV420 10-bit + CSPS	YUV4:2:0 image data
YUV422 8-bit	YUV4:2:2 image data
YUV422 10-bit	YUV4:2:2 image data
RGB565	RGB565 image data
RGB888	RGB888 image data
RGB888 + EXP32	RGB888 image data
RGB666 + EXP32_24	RGB666 image data
RGB666 + EXP32	RGB666 image data
RGB444 + EXP16	RGB444 image data
RGB555 + EXP16	RGB555 image data
RAW6 + EXP8	RAW Bayer, 6-bit image data
RAW7 + EXP8	RAW Bayer, 7-bit image data
RAW8	RAW Bayer, 8-bit image data
RAW8 + VP	RAW Bayer, 8-bit image data
RAW10	RAW Bayer, 10-bit image data
RAW10 + EXP16	RAW Bayer, 10-bit image data
RAW10 + VP	RAW Bayer, 10-bit image data
RAW12	RAW Bayer, 12-bit image data
RAW12 + EXP16	RAW Bayer, 12-bit image data
RAW12 + VP	RAW Bayer, 12-bit image data
RAW14	RAW Bayer, 14-bit image data
RAW14 + EXP16	RAW Bayer, 14-bit image data
RAW14 + VP	RAW Bayer, 14-bit image data
JPEG, 8-bit data	JPEG8

For more information on how the data formats are transmitted and how the data are stored in memory, see [Section 12.2.4.5.4, CSI2 Operating Modes](#).

#### 12.2.4.5.3.4 Synchronization Codes

Data reception from the image-sensor module uses four synchronization codes embedded in the serial bit-stream:

- FSC: Identifies the start of a new frame
- LSC: Identifies the start of a new line; received for every line
- LEC: Identifies the end of a line; received for every line
- FEC: Identifies the end of the last line and the end of the current frame

[Table 12-13](#) summarizes the synchronization code values.

**Table 12-13. Synchronization Codes**

Synchronization Code	Value	Comments
FSC	0x0	Mandatory
FEC	0x1	Mandatory
LSC	0x2	Optional
LEC	0x3	Optional
Reserved	0x4 to 0x7	Not used

#### 12.2.4.5.3.5 Generic Short Packet Codes

When the synchronization code value is between 0x8 and 0xF, the short packet is called a generic short packet. Short packets are not processed by the camera interface hardware. A generic short packet is stored in a register without the ECC and an interrupt can be generated. Therefore, generic short packets must be handled by software.

#### 12.2.4.5.3.6 Generic Long Packet Codes

The code value 0x10 indicates null packets, which can be received at any time. They are discarded by the protocol engine.

The code value 0x11 indicates blanking packets, which can be received at any time. They are discarded by the protocol engine.

The code value 0x12 indicates embedded 8-bit non-image data typically used for JPEG.

Code values from 0x13 to 0x17 are reserved.

#### 12.2.4.5.3.7 Frame Structure

Each frame consists of short packets to indicate start of frame and end of frame. Optional short packets for start of line and end of line can be sent by the image sensor.

Some information before and after the picture data can be sent as start-of-frame (SOF) and end-of-frame (EOF) information by the image sensor to the memory through the L3 port.

For each frame, the pixel data (arbitrary data or user-defined byte data) are valid only after an SOF short packet. If the data are invalid, they are discarded by the protocol engine.

A frame comprises embedded data and image-sensor data. [Figure 12-29](#) shows where the embedded data and image sensor data are in the frame. The following definitions apply:

- Zero or more SOF status lines (SOF lines) can be embedded at the beginning of a CSI2 frame.
- The image data comprises pixels of the same or different data formats.
- Zero or more EOF status lines (EOF lines) can be embedded at the end of a CSI2 frame.
- The SOF lines, pixel data, and EOF lines do not overlap.

**Figure 12-30. Digital Interlaced Video Frame (Informative)**

camisp-247

The period between the LEC and the new LSC is the line blanking period. The time between the FEC and the new FSC is the frame blanking period. The receiver works with the line blanking period set to 0.

#### 12.2.4.5.4 CSI2 Operating Modes

##### 12.2.4.5.4.1 YUV Operating Modes

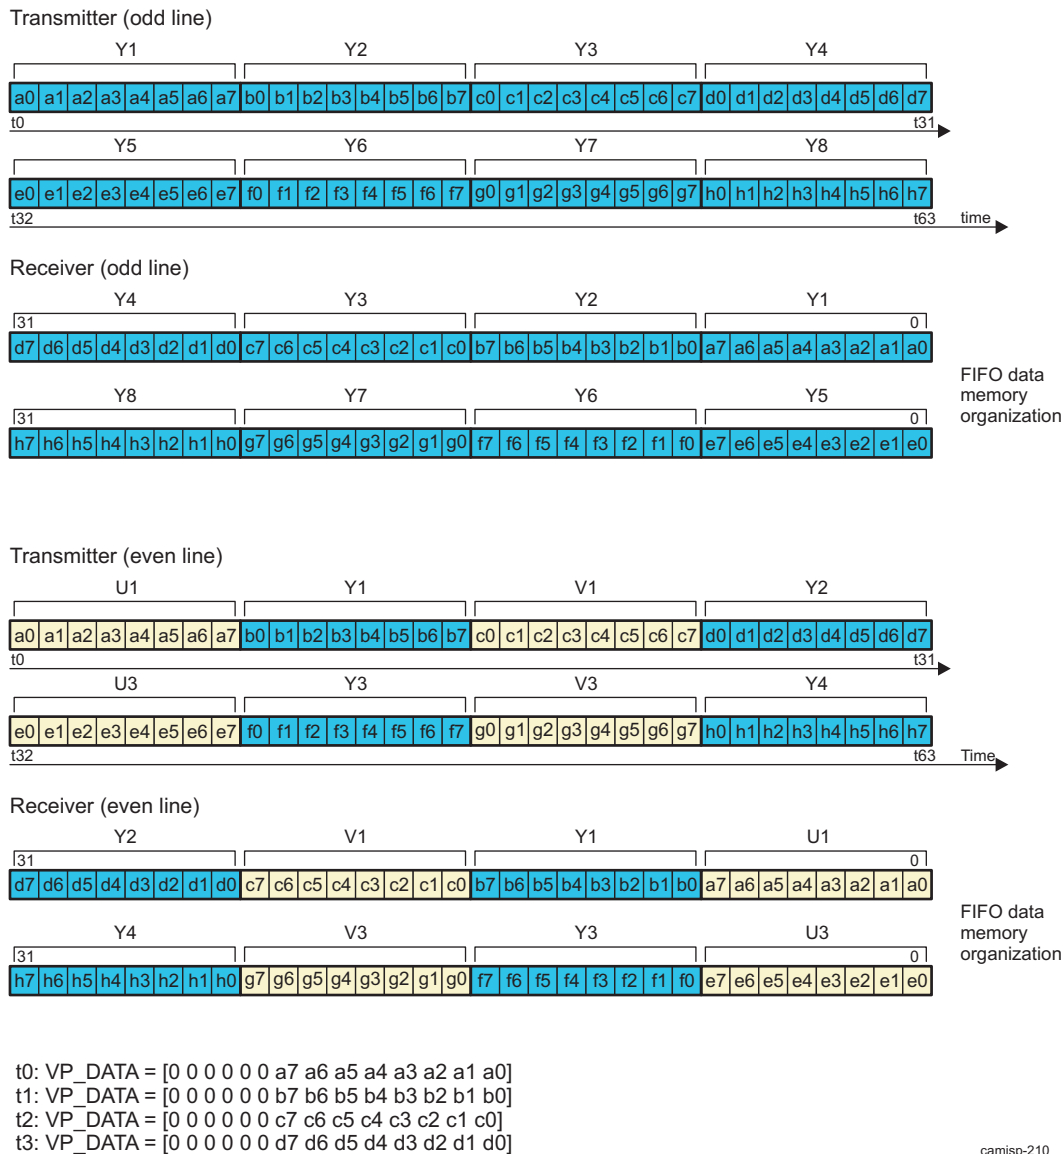

###### 12.2.4.5.4.1.1 YUV420 8-Bit

YUV420 8-bit data can be stored to memory in little-endian format. The line length sent through the CSI2 physical protocol is a multiple of 16 bits for odd lines and 32 bits for even lines.

For correct pixel reconstruction, the line length must be a multiple of 3\*32 bits and the number of lines must be even. [Figure 12-31](#) shows the storage format for YUV420 8-bit data.

Figure 12-31. YUV420 8-Bit

YUV420 8-bit

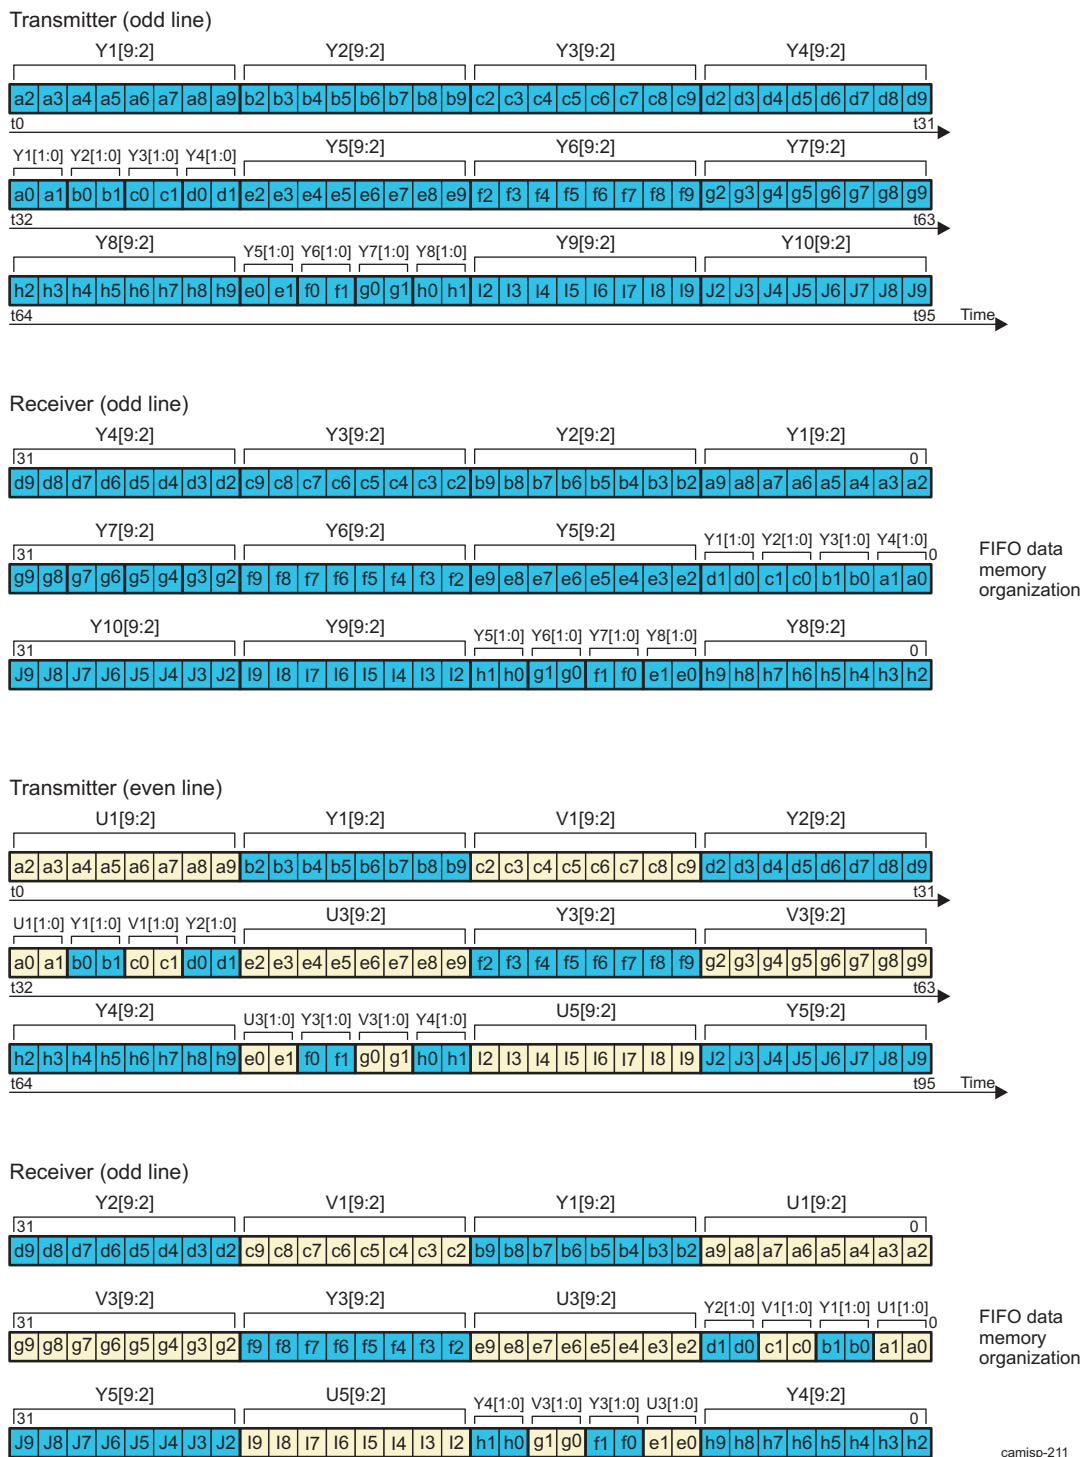

12.2.4.5.4.1.2 YUV420 10-Bit

YUV420 10-bit data can be stored to memory in little-endian format. The line length sent through the CSI2 physical protocol is a multiple of 40 bits for odd lines and 80 bits for even lines. Figure 12-32 shows the storage format for YUV420 10-bit data.

Figure 12-32. YUV420 10-Bit

YUV420 10-bit

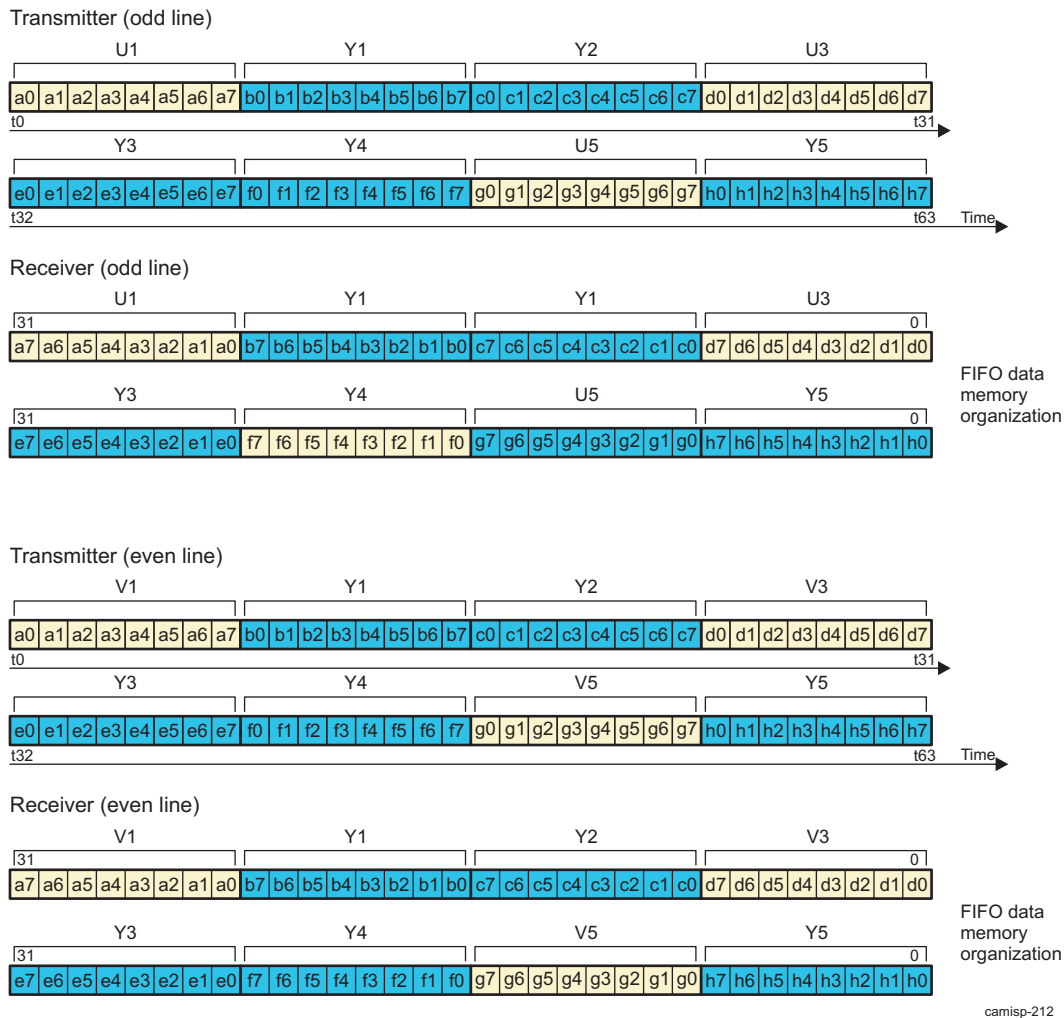

12.2.4.5.4.1.3 YUV420 8-Bit Legacy

YUV420 8-bit legacy data can be stored to memory in big-endian format. The line length sent through the CSI2 physical protocol is a multiple of 4 bytes. Figure 12-33 shows the storage format for YUV420 8-bit legacy data.

Figure 12-33. YUV420 8-Bit Legacy

YUV420 8-bit legacy

12.2.4.5.4.1.4 YUV420 8-Bit + CSPS

YUV420 8-bit CSPS data can be stored to memory in little-endian format. The line length sent through the CSI2 physical protocol is a multiple of 16 bits for odd lines and 32 bits for even lines.

For correct pixel reconstruction, the line length must be a multiple of 3\*32 bits and the number of lines must be even. Figure 12-34 shows the storage format for YUV420 8-bit + CSPS data.

Figure 12-34. YUV420 8-Bit + CSPS

YUV420 8-bit + CSPS

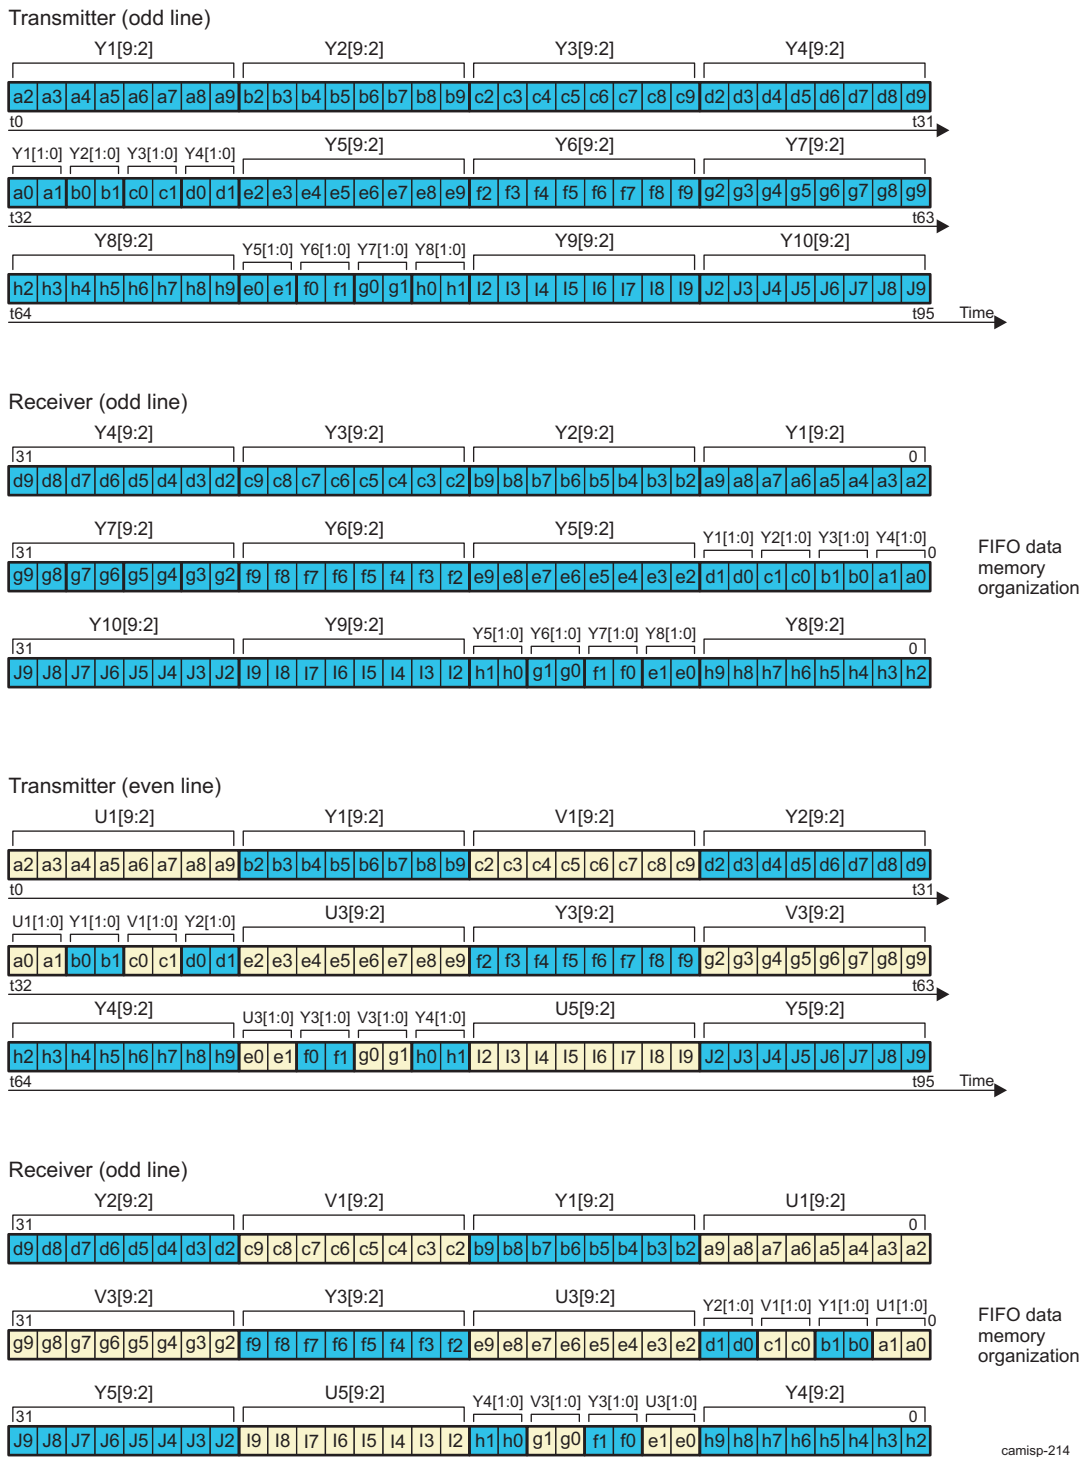

#### 12.2.4.5.4.1.5 YUV420 10-Bit + CSPS

YUV420 10-bit CSPS data can be stored to memory in little-endian format. The line length sent through the CSI2 physical protocol is a multiple of 40 bits for odd lines and 80 bits for even lines.

For correct pixel reconstruction, the line length must be a multiple of 3\*32 bits and the number of lines must be even. Figure 12-35 shows the storage format for YUV420 10-bit + CSPS data.

Figure 12-35. YUV420 10-Bit + CSPS

YUV420 10-bit + CSPS

12.2.4.5.4.1.6 YUV422 8-Bit

YUV422 data can be stored to memory in big-endian format. The line length sent through the CSI2 physical protocol is a multiple of 32 bits. Figure 12-36 shows the storage format for YUV422 8-bit data.

Figure 12-36. YUV422 8-Bit

YUV422 8-bit

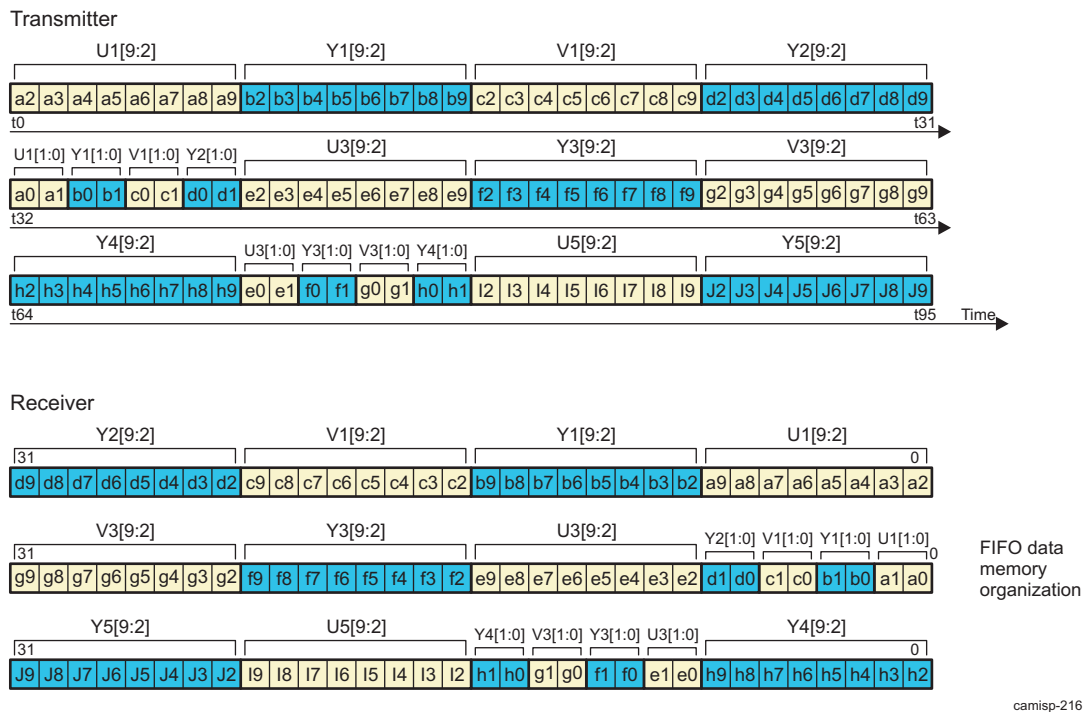

12.2.4.5.4.1.7 YUV422 10-Bit

YUV422 data can be stored to memory in little-endian format. The line length sent through the CSI2 physical protocol is a multiple of 40 bits. Figure 12-37 shows the storage format for YUV422 10-bit data.

Figure 12-37. YUV422 10-Bit

YUV422 10-bit

12.2.4.5.4.2 RGB Operating Modes

12.2.4.5.4.2.1 RGB565

RGB565 data is output to memory without data expansion. The line length sent through the CSI2 physical layer is always a multiple of 16 bits. Figure 12-38 shows the storage format for RGB565 data.

Figure 12-38. RGB565

12.2.4.5.4.2.2 RGB888

RGB888 data can be output to memory in two formats: with or without data expansion. If data expansion is used, the value of the 8 upper bits is programmable and can be set with an alpha value for computer graphics applications (the CSI2\_CTx\_CTRL3 [29:16] ALPHA bit field). Figure 12-39 shows the storage format for RGB888 data.

Figure 12-39. RGB888

RGB888

camisp-218

12.2.4.5.4.2.3 RGB666

RGB666 data is always output to memory with data expansion. The value of the 14 upper bits is programmable and can be set with an alpha value for computer graphics applications (the [CSI2\\_CTx\\_CTRL3](#) [29:16] ALPHA bit field). The line length sent through the CSI2 physical protocol is a multiple of 8 bits. Furthermore, the line length is a multiple of 9x8 bits to correctly finish the pixel reconstruction. [Figure 12-40](#) shows the storage format for RGB666 data.

Figure 12-40. RGB666

RGB666

camisp-219

#### 12.2.4.5.4.2.4 RGB444

RGB444 data is output to memory with data expansion. When data expansion is used, the value of the 4 upper bits is programmable and can be set with an alpha value for computer graphics applications (the CSI2\_CT<sub>x</sub>\_CTRL3[29:16] ALPHA bit field). Figure 12-41 shows the storage format for RGB444 data.

Figure 12-41. RGB444

#### 12.2.4.5.4.2.5 RGB555

RGB555 data is output to memory with data expansion. Figure 12-42 shows the storage format for RGB555 data.

Figure 12-42. RGB555

#### 12.2.4.5.4.3 RAW Bayer RGB Operating Modes

##### 12.2.4.5.4.3.1 RAW6

RAW6 data can be output only with data expansion. The line length sent through the CSI2 physical layer is a multiple of 8 bits. Furthermore, the line length is a multiple of 3x8 bits to correctly complete the pixel reconstruction (the lowest common multiple of 8 and 6 is 24, so 3x8 bits). Figure 12-43 shows the storage format for RAW6 data.

Figure 12-43. RAW6

RAW6

camisp-222

12.2.4.5.4.3.2 RAW7

RAW7 data can be output only with data expansion. The line length sent through the CSI2 physical layer is a multiple of 8 bits. Furthermore, the line length is a multiple of 7x8 bits to correctly complete the pixel reconstruction (the lowest common multiple of 8 and 7 is 56, so 7x8 bits). Figure 12-44 shows the storage format for RAW7 data.

Figure 12-44. RAW7

RAW7

12.2.4.5.4.3.3 RAW8

RAW8 data can be output only without data expansion. The line length sent through the CSI2 physical layer is always a multiple of 8 bits. Figure 12-45 shows the storage format for RAW8 data.

Figure 12-45. RAW8

RAW8

camisp-224

12.2.4.5.4.3.4 RAW10

RAW10 data can be output memory in two formats: with or without data expansion. It can be sent to video port too. If data expansion is used, the 10-bit data are padded with 0s on a 16-bit word. The line length sent through the CSI2 physical layer is a multiple of 8 bits. Furthermore, the line length is a multiple of 5x8 bits to correctly complete the pixel reconstruction (the lowest common multiple of 8 and 10 is 40, so 5x8 bits). Figure 12-46 shows the storage format for RAW10 data.

### 12.2.4.5.4.3.5 RAW12

RAW12 data can be output to memory in two formats: with or without data expansion. It can be sent to video port too. If data expansion is used, the 12-bit data are padded with 0s on a 16-bit word. The line length sent through the CSI2 physical layer is a multiple of 8 bits. Furthermore, the line length is a multiple of 3x8 bits to correctly complete the pixel reconstruction (the lowest common multiple of 8 and 12 is 24, so 3x8 bits). Figure 12-47 shows the storage format for RAW12 data.

Figure 12-47. RAW12

12.2.4.5.4.3.6 RAW14

RAW14 data can be output to memory in two formats: with or without data expansion. It can be sent to video port too. If data expansion is used, the 14-bit data are padded with 0s on a 16-bit word. The line length sent through the CSI2 physical layer is a multiple of 8 bits. Furthermore, the line length is a multiple of 7x8 bits to correctly complete the pixel reconstruction (the lowest common multiple of 8 and 14 is 56, so 7x8 bits). Figure 12-48 shows the storage format for RAW14 data.

## 12.3 Camera ISP Integration

Figure 12-50 shows the camera ISP integration.

Figure 12-50. Camera ISP Integration

### 12.3.1 Clocking, Reset, and Power-Management Scheme

#### 12.3.1.1 Clocks

There are four clock domains in the camera ISP:

- Functional clock domain
- Interface clock domain
- Serial sensor clock domain

- Parallel sensor clock domain

### 12.3.1.1.1 Clock Tree

Figure 12-51 shows the clock tree for the camera ISP module.

### 12.3.1.1.2 Clock Descriptions

Table 12-14 describes the camera ISP clocks.

**Table 12-14. Clock Descriptions**

Signal Name	I/O	Description
CAM_FCLK	Input	Functional clock (L3 interconnect clock domain) Functional clock domain.
CAM_ICLK	Input	Interface clock (L4 interconnect clock domain) Interface clock domain.
CAM_MCLK <sup>(1)</sup>	Input	Internal clock from PRCM at 216 MHz. The CAM_MCLK is used by the clock generator to generate cam_xclka and cam_xclkb. It is also used by the control signal generator to generate cam_shutter, cam_strobe, and cam_global_reset. For more information, see Section 12.4.4, <i>Timing Control</i> .
cam_xclka	Output	External clock for the image-sensor module. For serial or parallel sensor.
cam_xclkb	Output	External clock for the image-sensor module. For serial or parallel sensor.
cam_pclk	Input	Parallel mode: pixel clock for parallel input data. The data on the parallel interface are presented on cam_d, one pixel for every cam_pclk rising or falling edge. Parallel sensor clock domain.
CSI2_96M_FCLK	Input	CSI2 functional clock driven by CM_FCLKEN_CAM[1] EN_CSI2.

<sup>(1)</sup> The CAM\_MCLK frequency can be less than, or equal to 216 MHz.

### 12.3.1.1.3 Clock Configuration

- CSI2\_96M\_FCLK is the CSI2 functional clock running at 96 MHz and enabled when CM\_FCLKEN\_CAM[1] EN\_CSI2 = 1
- CAM\_FCLK control and settings

The CAM\_FCLK clock runs at the device L3 clock frequency.

The CAM\_FCLK source is the PRCM CAM\_L3\_ICLK output.

When the camera ISP no longer needs CAM\_FCLK, the software can disable it at PRCM level by setting the PRCM.CM\_ICLK\_CAM [0] EN\_CAM bit to 0x0. Note that the clock is not effectively shut down until the camera ISP module has reached the IDLE state (that is, it does not generate anymore traffic on the device interconnect and is internally idled). For information, note that an automatic HW handshake protocol takes place between the camera ISP and the PRCM to prevent CAM\_FCLK from being cut while the module is processing or transferring data.

An autoidle mode can be activated for this clock (PRCM.CM\_AUTOIDLE\_CAM [0] AUTO\_CAM bit set to 1). This allows global management of the CAM\_FCLK clock along with the CAM power domain at PRCM level. For more information, see [Chapter 4, Power, Reset, and Clock Management](#).

- CAM\_ICLK control and settings:

CAM\_ICLK is the interface clock. It runs at device L4 interconnect clock speed and triggers access to the camera ISP L4 interface. Its source is the PRCM CAM\_L4\_ICLK output.

When the camera ISP no longer needs CAM\_ICLK, the software can disable it at PRCM level by setting to 0x0 the PRCM.CM\_ICLK\_CAM [0] EN\_CAM bit. Note that the clock is not effectively shut down until the camera ISP module has reached the IDLE state (that is, it does not generate anymore traffic on the device interconnect and is internally idled). As information, note an automatic HW handshake protocol takes place between the camera ISP and the PRCM to prevent CAM\_ICLK from being cut while the module is processing or transferring data.

An autoidle mode can be activated for this clock (PRCM.CM\_AUTOIDLE\_CAM [0] AUTO\_CAM bit set to 1). This allows global management of the CAM\_ICLK clock along with the CAM power domain at PRCM level. For more information, see [Chapter 4, Power, Reset, and Clock Management](#).

- CAM\_MCLK control and settings:

The source for CAM\_MCLK is the PRCM CAM\_MCLK output. It is generated through a peripheral DPLL and its frequency can be adjusted using the PRCM.CM\_CLKSEL\_CAM CLKSEL\_CAM bit field. When the module no longer needs it, it can be disabled at PRCM level by setting the PRCM.CM\_FCLKEN\_CAM EN\_CAM bit to 0x0. Note that the PRCM register bit setting has a direct effect on the clock; in other terms, there is no HW handshake protocol to ensure whether the clock can be cut regarding the camera ISP activity: as soon as the bit is set to 0x0, CAM\_MCLK is shut down.

- cam\_xclka and cam\_xclkb control and settings:

cam\_xclka and cam\_xclkb are generated inside the camera ISP module from CAM\_MCLK clock input. [Table 12-15](#) and [Table 12-16](#) give the settings of the related bit fields.

**Table 12-15. cam\_xclka Configuration**

ref_clk	CAM.TCTRL_CTRL[4:0] DIVA field	cam_xclka
CAM_MCLK	0x0	Stable low level. Divider disabled.
	0x1	Stable high level. Divider disabled.
	0x2	CAM_MCLK/2
	...	...
	0x1F	CAM_MCLK

**Table 12-16. cam\_xclkb Configuration**

ref_clk	CAM.TCTRL_CTRL[9:5] DIVB field	cam_xclkb
CAM_MCLK	0x0	Stable low level. Divider disabled.
	0x1	Stable high level. Divider disabled.
	0x2	CAM_MCLK/2
	...	...

**Table 12-16. cam\_xclkb Configuration (continued)**

ref_clk	CAM.TCTRL_CTRL[9:5] DIVB field	cam_xclkb
	0x1F	CAM_MCLK

### 12.3.1.2 Power Management

Power consumption can be reduced at two different levels:

- A local power-management optimization
- A system power management

#### 12.3.1.2.1 Local Power Management

To optimize power consumption, a local autoidle feature is implemented on the CAM\_ICLK interface clock at camera ISP module level. By enabling this autoidle feature, CAM\_ICLK is automatically gated at the module boundary as soon as it is not required and restarted without any latency when needed again. This allows power saving when the module is not involved in any transfer from/to the device interconnect. This autoidle feature is enabled by setting:

- [ISP\\_SYSCONFIG](#) [0] AUTO\_IDLE bit to 1
- [CSI1\\_SYSCONFIG](#) [0] AUTO\_IDLE bit to 1
- [CSI2\\_SYSCONFIG](#) [0] AUTO\_IDLE bit to 1
- [MMU\\_SYSCONFIG](#) [0] AUTOIDLE bit to 1
- [ISP\\_CTRL](#) [21] SBL\_AUTOIDLE bit to 1

The decision to gate the interconnect clock is based on interface activity, regardless of hardware handshake protocols.

After a reset, this mode is enabled, by default.

---

**NOTE:** It is recommended that this mode be enabled to reduce power consumption.

---

#### 12.3.1.2.2 System Power Management

As part of the system power management scheme, the camera ISP module interacts with the PRCM through an automatic standby hardware protocol that allows dynamic power savings at CAMERA power domain level.

Being an initiator on the L3 interconnect, the camera ISP module alerts the PRCM as soon as it is ready to switch to a lower power state. Prior to any power state change to the CAMERA power domain, the PRCM first shuts off the camera clocks, depending on the camera ISP behavior and the clock settings at PRCM level. Namely, as soon as the camera ISP is ready to go to STANDBY, it asserts an automatic HW STANDBY request to the PRCM, which shuts down the clocks if they have been previously disabled by software and then potentially change the CAMERA power domain state. Refer to [Chapter 4, Power, Reset, and Clock Management](#) for further details.

When it goes to standby, the camera ISP module alerts the PRCM differently, depending on the [ISP\\_SYSCONFIG](#) [13:12] MIDDLE\_MODE bit field settings. The entry conditions for the camera ISP to go into standby mode are:

- The module has finished any current transaction and does not generate any more traffic on the interconnect.
- The module is idle (on-going transactions are finished).

The MIDDLE\_MODE bit field allows the following settings for the camera ISP module:

- Force standby

The camera ISP is set to force standby when MIDDLE\_MODE is set to 0x0. In this mode, the camera ISP module asserts its HW standby request to the PRCM as soon as it is disabled. Namely, the camera ISP is disabled when the following bit fields are set to 0x0:

- [ISP\\_CTRL](#) [13] RSZ\_CLK\_EN
- [ISP\\_CTRL](#) [12] PRV\_CLK\_EN
- [ISP\\_CTRL](#) [11] HIST\_CLK\_EN
- [ISP\\_CTRL](#) [10] H3A\_CLK\_EN
- [ISP\\_CTRL](#) [8] CCDC\_CLK\_EN

Moreover, CSIa must also be disabled by setting the related [CSI2\\_CTRL](#)[0] IF\_EN bits to 0x0 and CSIb must also be disabled by setting the related [CSI1\\_CTRL](#) [0] IF\_EN bits to 0x0.

- No standby

The camera ISP is set to no standby when [MIDDLE\\_MODE](#) is set to 0x1. In this mode, the camera ISP module never asserts its standby request to the PRCM. Note that this also prevents the CAMERA power domain from going to a lower power state. Refer to [Chapter 4, Power, Reset, and Clock Management](#), for further details.

- Smart standby

The camera ISP module is set to smart standby when [MIDDLE\\_MODE](#) is set to 0x2. In this mode, the camera ISP module asserts its HW standby request to the PRCM according with its internal activity (namely, when there is no more activity on the camera ISP master interface, that is, when there is no more data in the central resource buffer).

---

**NOTE:** CSI1 must also be configured to smart standby mode when the camera ISP is set to smart standby ( [CSI1\\_SYSCONFIG](#) [13:12] [MSTANDBY\\_MODE](#) set to 0x2).

CSI2 must also be configured to smart standby mode when the camera ISP is set to smart standby ([CSI2\\_SYSCONFIG](#)[13:12] [MSTANDBY\\_MODE](#) set to 0x2).

---

A standby request asserted to the PRCM does not necessarily lead to [CAM\\_FCLK](#) and [CAM\\_ICLK](#) being cut. The PRCM must also be set correctly for that purpose.

The clocks are cut, allowing a CAMERA power state change if:

- [PRCM.CM\\_ICLKEN\\_CAM](#)[0] [EN\\_CAM](#) = 0 and [PRCM.CM\\_FCLKEN\\_CAM](#)[0] [EN\\_CAM](#) = 0
- [PRCM.CM\\_FCLKEN\\_CAM](#)[0] [EN\\_CAM](#) = 0, ([PRCM.CM\\_ICLKEN\\_CAM](#)[0] [EN\\_CAM](#) =1, [PRCM.CM\\_AUTOIDLE\\_CAM](#)[0] = 1, and a domain transition is required at PRCM level)

See [Chapter 4, Power, Reset, and Clock Management](#), for further details.

### 12.3.1.3 Power Domain

The camera ISP belongs to the CAMERA power domain. For more information about the CAMERA power domain, see [Chapter 4, Power, Reset, and Clock Management](#).

### 12.3.1.4 Resets

#### 12.3.1.4.1 Hardware Reset

Global reset of the camera ISP module is accomplished by activation of the [CAM\\_RST](#) signal in the CAMERA domain (for more information, see [Chapter 4, Power, Reset, and Clock Management](#)).

#### 12.3.1.4.2 Software Reset

A global software reset can be accomplished by setting the camera ISP [ISP\\_SYSCONFIG](#) [1] [SOFT\\_RESET](#) bit to 1. Setting this bit enables active software reset functionality equivalent to hardware reset for the entire module, including CSI1 and CSI2 receivers.

**NOTE:** The CSI1 receiver accepts a general software reset, propagated through the hierarchy. This reset can be performed to initialize the module and has the same effect as a hardware reset. The CSI1 receiver can be reset by writing CSI1\_SYSCONFIG [1] SOFT\_RESET bit to 1. The software can monitor the CSI1\_SYSSTATUS [0] RESET\_DONE status bit to wait for the completion of the reset procedure.

If after 5 reads, CSI1\_SYSSTATUS [0] RESET\_DONE still returns 0, it can be assumed that an error occurred during the reset stage.

The CSI2 receiver accepts a general software reset, propagated through the hierarchy. This reset can be performed to initialize the module and has the same effect as a hardware reset. The CSI2 receiver can be reset by writing CSI2\_SYSCONFIG [1] SOFT\_RESET bit to 1. The software can monitor the CSI2\_SYSSTATUS [0] RESET\_DONE status bit to wait for the completion of the reset procedure.

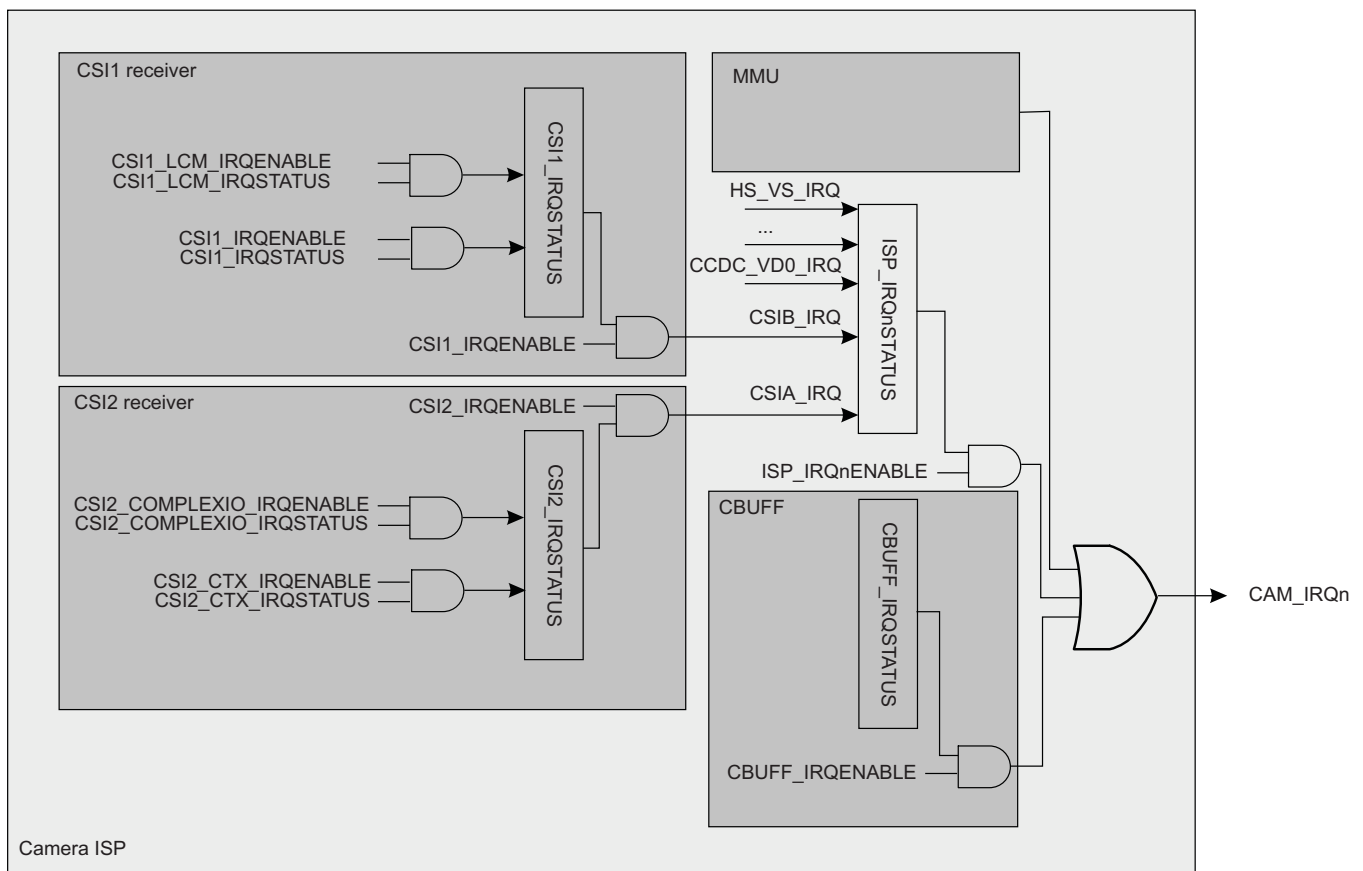

If after 5 reads, CSI2\_SYSSTATUS [0] RESET\_DONE still returns 0, it can be assumed that an error occurred during the reset stage.

### 12.3.2 Hardware Requests

#### 12.3.2.1 Interrupt Requests

Figure 12-52 shows the interrupt generation tree of the camera subsystem.

Figure 12-52. Interrupt Generation Tree

camisp-305

The camera ISP can generate two interrupts:

- CAM\_IRQ0 is an interrupt to the MPU subsystem interrupt controller. It is mapped on M\_IRQ\_24.
- CAM\_IRQ1 is an interrupt to the IVA2.2 subsystem interrupt controller. It is mapped on IVA2\_IRQ[11].

Table 12-17 summarizes events that cause interrupts.

**Table 12-17. Camera ISP Interrupts**

Event	Mask	Description
<a href="#">ISP_IRQ0STATUS</a> [31] <a href="#">HS_VS_IRQ</a>	<a href="#">ISP_IRQ0ENABLE</a> [31] <a href="#">HS_VS_IRQ</a>	HS or VS synchronization event: triggered if a rising or falling edge is detected on the HS or VS signal. The rising or falling edge and the HS or VS signal selection are chosen with the <a href="#">ISP_CTRL</a> [15:14] SYNC_DETECT bit field. <sup>(1)</sup>
<a href="#">ISP_IRQ0STATUS</a> [28] <a href="#">MMU_ERR_IRQ</a>	<a href="#">ISP_IRQ0ENABLE</a> [28] <a href="#">MMU_ERR_IRQ</a>	MMU error
<a href="#">ISP_IRQ0STATUS</a> [25] <a href="#">OVF_IRQ</a>	<a href="#">ISP_IRQ0ENABLE</a> [25] <a href="#">OVF_IRQ</a>	Central-resource SBL overflow: triggered when one of the buffers in the central-resource SBL overflows
<a href="#">ISP_IRQ0STATUS</a> [24] <a href="#">RSZ_DONE_IRQ</a>	<a href="#">ISP_IRQ0ENABLE</a> [24] <a href="#">RSZ_DONE_IRQ</a>	RESIZER module. Resizer processing-done event: Triggered at the end of the frame when processing is complete for the current frame. It applies to one-shot and continuous modes.
<a href="#">ISP_IRQ0STATUS</a> [21] <a href="#">CBUFF_IRQ</a>	<a href="#">ISP_IRQ0ENABLE</a> [24] <a href="#">CBUFF_IRQ</a>	CBUFF module event. See <a href="#">CBUFF_IRQSTATUS</a> to know which interrupt it is.
<a href="#">ISP_IRQ0STATUS</a> [20] <a href="#">PRV_DONE_IRQ</a>	<a href="#">ISP_IRQ0ENABLE</a> [20] <a href="#">PRV_DONE_IRQ</a>	PREVIEW module: Processing-done event: triggered at the end of the frame when processing is complete for the current frame
<a href="#">ISP_IRQ0STATUS</a> [19] <a href="#">CCDC_LSC_PREFETCH_ERROR</a>	<a href="#">ISP_IRQ0ENABLE</a> [19] <a href="#">PRV_DONE_IRQ</a>	CCDC module. The prefetch error indicates when the gain table was read too slowly from memory. When this event is pending, the module goes into transparent mode (output = input). Normal operation can be resumed at the start of the next frame after: 1) Clearing this event 2) Disabling the LSC module 3) Enabling it
<a href="#">ISP_IRQ0STATUS</a> [18] <a href="#">CCDC_LSC_PREFETCH_COMPLETED</a>	<a href="#">ISP_IRQ0ENABLE</a> [18] <a href="#">CCDC_LSC_PREFETCH_COMPLETED</a>	CCDC module. Indicates the current state of the prefetch buffer. Can be used to start sending the data once the buffer is full to minimize the risk of an underflow. This event is triggered when the buffer contains 3 full pixel rows. It can be used to minimize buffer underflow risks.
<a href="#">ISP_IRQ0STATUS</a> [17] <a href="#">CCDC_LSC_DONE</a>	<a href="#">ISP_IRQ0ENABLE</a> [17] <a href="#">CCDC_LSC_DONE</a>	CCDC module. The event is triggered when the internal state of LSC toggles from BUSY to IDLE. This happens when the LSC module has completed processing the current frame.
<a href="#">ISP_IRQ0STATUS</a> [16] <a href="#">HIST_DONE_IRQ</a>	<a href="#">ISP_IRQ0ENABLE</a> [16] <a href="#">HIST_DONE_IRQ</a>	HIST module. Processing-done event: triggered at the end of the frame when processing is complete for the current frame
<a href="#">ISP_IRQ0STATUS</a> [13] <a href="#">H3A_AWB_DONE_IRQ</a>	<a href="#">ISP_IRQ0ENABLE</a> [13] <a href="#">H3A_AWB_DONE_IRQ</a>	H3A module. Auto exposure and auto white balance processing done event: Triggered at the end of the frame when processing is complete for the current frame
<a href="#">ISP_IRQ0STATUS</a> [12] <a href="#">H3A_AF_DONE_IRQ</a>	<a href="#">ISP_IRQ0ENABLE</a> [12] <a href="#">H3A_AF_DONE_IRQ</a>	H3A module. Autofocus processing-done event: triggered at the end of the frame when processing is complete for the current frame
<a href="#">ISP_IRQ0STATUS</a> [11] <a href="#">CCDC_ERR_IRQ</a>	<a href="#">ISP_IRQ0ENABLE</a> [11] <a href="#">CCDC_ERR_IRQ</a>	CCDC module. Faulty-pixel correction error: Faulty-pixel correction memory underflow. Triggered to signal an error in the faulty-pixel correction logic. The hardware did not have time to read the faulty-pixel LUT from external memory in time.
<a href="#">ISP_IRQ0STATUS</a> [10] <a href="#">CCDC_VD2_IRQ</a>	<a href="#">ISP_IRQ0ENABLE</a> [10] <a href="#">CCDC_VD2_IRQ</a>	CCDC module. Programmable event 2: triggered by the falling edge on the cam_wen signal. This event is not programmable.

<sup>(1)</sup> This event is detected on the incoming HS/VS signals before the CCDC. Therefore, it cannot be used in BT656 mode.

**Table 12-17. Camera ISP Interrupts (continued)**

Event	Mask	Description
<a href="#">ISP_IRQ0STATUS</a> [9] CCDC_VD1_IRQ	<a href="#">ISP_IRQ0ENABLE</a> [9] CCDC_VD1_IRQ	CCDC module. Programmable event 1: triggered after a programmable number of horizontal lines is received after a VS pulse
<a href="#">ISP_IRQ0STATUS</a> [8] CCDC_VD0_IRQ	<a href="#">ISP_IRQ0ENABLE</a> [8] CCDC_VD0_IRQ	CCDC module. Programmable event 0: triggered after a programmable number of horizontal lines is received after a VS pulse
<a href="#">ISP_IRQ0STATUS</a> [4] CSIB_IRQ	<a href="#">ISP_IRQ0ENABLE</a> [4] CSIB_IRQ	CS1b RECEIVER module event. See <a href="#">CSI1_IRQSTATUS</a> to know which interrupt it is.
<a href="#">ISP_IRQ0STATUS</a> [3] CSIB_LCM_IRQ	<a href="#">ISP_IRQ0ENABLE</a> [3] CSIB_LCM_IRQ	CS1b RECEIVER module event on memory channel.
<a href="#">ISP_IRQ0STATUS</a> [0] CSIA_IRQ	<a href="#">ISP_IRQ0ENABLE</a> [0] CSIA_IRQ	CS1a RECEIVER module event. See <a href="#">CSI2_IRQSTATUS</a> to know which interrupt it is.

---

**NOTE:** n is equal to 0 or 1.

l is equal to 01 or 23.

---

[Table 12-18](#) summarizes the CBUFF interrupts.

**Table 12-18. CBUFF Interrupt Details**

Event	Mask	Description
<a href="#">CBUFF_IRQSTATUS</a> [5] IRQ_CBUFF1_OVR	<a href="#">CBUFF_IRQENABLE</a> [5] IRQ_CBUFF1_OVR	Buffer overflow event: The generation of this event depends on the <a href="#">CBUFFx_CTRL.ALLOW_NW_EQ_CR</a> flag and the circular buffer mode (read or write). This event indicates a bandwidth mismatch between data producer and data consumer. When it occurs, CBUFFx does NOT go into error state. However, the data in the physical buffer is very likely to be corrupted.

**Table 12-18. CBUFF Interrupt Details (continued)**

Event	Mask	Description
<a href="#">CBUFF_IRQSTATUS</a> [4] <a href="#">IRQ_CBUFF1_INVALID</a>	<a href="#">CBUFF_IRQENABLE</a> [4] <a href="#">IRQ_CBUFF1_INVALID</a>	<p>Invalid access:</p> <ul style="list-style-type: none"> <li>Camera controller writes the virtual space of CBUFFx in read mode.</li> <li>Camera controller reads the virtual space of CBUFFx in write mode.</li> <li>HW writes the virtual space of circular buffer x outside the CW or NW window in write mode.</li> <li>HW reads the virtual space of circular buffer x outside the CW or NW window in read mode.</li> <li>NW full</li> <li>CPU write the DONE bit when physical buffers are not ready for the CPU.</li> </ul> <p>This event indicates a wrong configuration of the circular buffer, the camera ISP, or bogus software. When it occurs, CBUFFx goes into an error state. In this state all accesses to the virtual space of CBUFFx are cancelled: they are not forwarded to the physical space. The purpose is to prevent corruption of the physical memory.</p> <p>The error state can be left by disabling the CBUFFx and reenabling it. Before doing so, the SW must ensure that there are no more outstanding requests to the virtual space of CBUFFx.</p>
<a href="#">CBUFF_IRQSTATUS</a> [3] <a href="#">IRQ_CBUFF1_READY</a>	<a href="#">CBUFF_IRQENABLE</a> [3] <a href="#">IRQ_CBUFF1_READY</a>	The CPUW1 physical buffer is ready to be accessed by the CPU.
<a href="#">CBUFF_IRQSTATUS</a> [2] <a href="#">IRQ_CBUFF0_OVR</a>	<a href="#">CBUFF_IRQENABLE</a> [2] <a href="#">IRQ_CBUFF0_OVR</a>	Buffer overflow event. See description of <a href="#">IRQ_CBUFF1_OVR</a> event.
<a href="#">CBUFF_IRQSTATUS</a> [1] <a href="#">IRQ_CBUFF0_INVALID</a>	<a href="#">CBUFF_IRQENABLE</a> [1] <a href="#">IRQ_CBUFF0_INVALID</a>	Invalid access. See description of <a href="#">IRQ_CBUFF1_INVALID</a> event.
<a href="#">CBUFF_IRQSTATUS</a> [0] <a href="#">IRQ_CBUFF0_READY</a>	<a href="#">CBUFF_IRQENABLE</a> [0] <a href="#">IRQ_CBUFF0_READY</a>	The CPUW1 physical buffer is ready to be accessed by the CPU.

[Table 12-19](#) describes the CSI1 receiver interrupts.

**Table 12-19. CSI1 Receiver Interrupt Details**

Event	Mask	Description
<a href="#">CSI1_IRQSTATUS</a> [11] <a href="#">FS_IRQ</a>	<a href="#">CSI1_IRQENABLE</a> [11] <a href="#">FS_IRQ</a>	Frame-start synchronization code detection
<a href="#">CSI1_IRQSTATUS</a> [10] <a href="#">LE_IRQ</a>	<a href="#">CSI1_IRQENABLE</a> [10] <a href="#">LE_IRQ</a>	Line-end sync code detection
<a href="#">CSI1_IRQSTATUS</a> [9] <a href="#">LS_IRQ</a>	<a href="#">CSI1_IRQENABLE</a> [9] <a href="#">LS_IRQ</a>	Line-start sync code detection
<a href="#">CSI1_IRQSTATUS</a> [8] <a href="#">FE_IRQ</a>	<a href="#">CSI1_IRQENABLE</a> [8] <a href="#">FE_IRQ</a>	Frame-end sync code detection
<a href="#">CSI1_IRQSTATUS</a> [7] <a href="#">COUNT_IRQ</a>	<a href="#">CSI1_IRQENABLE</a> [7] <a href="#">COUNT_IRQ</a>	Frame counter reached
<a href="#">CSI1_IRQSTATUS</a> [5] <a href="#">FIFO_OVF_IRQ</a>	<a href="#">CSI1_IRQENABLE</a> [5] <a href="#">FIFO_OVF_IRQ</a>	FIFO overflow error
<a href="#">CSI1_IRQSTATUS</a> [3] <a href="#">FSP_IRQ</a>	<a href="#">CSI1_IRQENABLE</a> [3] <a href="#">FSP_IRQ</a>	FSP error
<a href="#">CSI1_IRQSTATUS</a> [2] <a href="#">FW_IRQ</a>	<a href="#">CSI1_IRQENABLE</a> [2] <a href="#">FW_IRQ</a>	Frame-width error
<a href="#">CSI1_IRQSTATUS</a> [1] <a href="#">FSC_IRQ</a>	<a href="#">CSI1_IRQENABLE</a> [1] <a href="#">FSC_IRQ</a>	False sync code error
<a href="#">CSI1_IRQSTATUS</a> [0] <a href="#">SSC_IRQ</a>	<a href="#">CSI1_IRQENABLE</a> [0] <a href="#">SSC_IRQ</a>	Shifted sync code error: This interrupt cannot be triggered if the complex I/O is set in parallel mode ( <a href="#">CSI1_CTRL</a> [2] <a href="#">IO_OUT_SEL</a> = 1).
<a href="#">CSI1_LCM_IRQSTATUS</a> [1] <a href="#">LCM_OCPERROR</a>	<a href="#">CSI1_LCM_IRQENABLE</a> [1] <a href="#">LCM_OCPERROR</a>	An OCP error occurred on the master read port.

**Table 12-19. CSI1 Receiver Interrupt Details (continued)**

Event	Mask	Description
CSI1_LCM_IRQSTATUS [0] LCM_EOF	CSI1_LCM_IRQENABLE [0] LCM_OEF	Memory read channel– End of frame: This interrupt is triggered when a frame has been completely read from memory.

Table 12-20 shows CSI2 receiver event generation through the CSI2 interrupt status and interrupt enable registers.

**Table 12-20. CSI2 Receiver Event Generation (CSI2\_IRQSTATUS and CSI2\_IRQENABLE Registers)**

Bit	Event	Clear	Description
0	CONTEXT0	No	At least one interrupt event enabled from Context 0 occurred (see Table 12-22).
1	CONTEXT1	No	At least one interrupt event enabled from Context 1 occurred (see Table 12-22).
2	CONTEXT2	No	At least one interrupt event enabled from Context 2 occurred (see Table 12-22).
3	CONTEXT3	No	At least one interrupt event enabled from Context 3 occurred (see Table 12-22).
4	CONTEXT4	No	At least one interrupt event enabled from Context 4 occurred (see Table 12-22).
5	CONTEXT5	No	At least one interrupt event enabled from Context 5 occurred (see Table 12-22).
6	CONTEXT6	No	At least one interrupt event enabled from Context 6 occurred (see Table 12-22).
7	CONTEXT7	No	At least one interrupt event enabled from Context 7 occurred (see Table 12-22).
8	FIFO_OVF_IRQ	Yes	FIFO overflow error: This interrupt is triggered on detection of a FIFO overflow. An overflow can occur if there is a mismatch between the data input and output rates. A reset of the module is required to restart correctly.
9	COMPLEXIO_ERR_IRQ	No	Error signaling from complex I/O: This interrupt is triggered when any error is received from the complex I/O (events are defined in CSI2_COMPLEXIO1_IRQSTATUS [see Table 12-21]).
11	ECC_NO_CORRECTION_IRQ	Yes	ECC was not used to correct the header because the error is larger than 1 bit (short and long packets).
12	ECC_CORRECTION_IRQ	Yes	ECC was used to correct a 1-bit error (short packet only).
13	SHORT_PACKET_IRQ	Yes	Short packet reception (other than sync events: line start, line end, frame start, and frame end; only data types between 0x8 and 0xF are considered).
14	OCP_ERR_IRQ	Yes	OCP error

Table 12-21 shows CSI2 receiver event generation through the CSI2 complex I/O interrupt status and interrupt enable registers.

**Table 12-21. CSI2 Receiver Event Generation (CSI2\_COMPLEXIO\_IRQSTATUS and CSI2\_COMPLEXIO\_IRQENABLE Registers)**

Bit	Event	Clear	Description
0	ERRSOTHS1	Yes	Start of transmission error for lane 1
1	ERRSOTHS2	Yes	Start of transmission error for lane 2
2	ERRSOTHS3	Yes	Start of transmission error for lane 3
5	ERRSOTSYNCHS1	Yes	Start of transmission sync error for lane 1
6	ERRSOTSYNCHS2	Yes	Start of transmission sync error for lane 2
7	ERRSOTSYNCHS3	Yes	Start of transmission sync error for lane 3
10	ERRESC1	Yes	Escape entry error for lane 1
11	ERRESC2	Yes	Escape entry error for lane 2

**Table 12-21. CSI2 Receiver Event Generation (CSI2\_COMPLEXIO\_IRQSTATUS and CSI2\_COMPLEXIO\_IRQENABLE Registers) (continued)**

Bit	Event	Clear	Description
12	ERRESC3	Yes	Escape entry error for lane 3
15	ERRCONTROL1	Yes	Control error for lane 1
16	ERRCONTROL2	Yes	Control error for lane 2
17	ERRCONTROL3	Yes	Control error for lane 3
20	STATEULPM1	Yes	Lane 1 in ULPM
21	STATEULPM2	Yes	Lane 2 in ULPM
22	STATEULPM3	Yes	Lane 3 in ULPM
25	STATEALLULPMENTER	Yes	All active lanes are entering in ULPM.
26	STATEALLULPMEXIT	Yes	At least one active lane exited the ULPM.

As the CSI2 receiver supports eight contexts, the [CSI2\\_CTX\\_IRQSTATUS](#) and [CSI2\\_CTX\\_IRQENABLE](#) registers are present eight times (one time per context).

The events are generated only for the enabled context(s). [Table 12-22](#) describes the CSI2 receiver event generation through the CTX interrupt status and interrupt enable registers.

**Table 12-22. CSI2 Receiver Event Generation (CSI2\_CTX\_IRQSTATUS and CSI2\_CTX\_IRQENABLE Registers)**

Bit	Event	Clear	Description
0	FS_IRQ	Yes	Frame start: This interrupt is triggered on the detection of a frame-start synchronization code into the CSI2 data stream.
1	FE_IRQ	Yes	Frame end: This interrupt is triggered on the detection of a frame-end synchronization code into the CSI2 data stream.
2	LS_IRQ	Yes	Line start: This interrupt is triggered on the detection of a line-start synchronization code into the CSI2 data stream.
3	LE_IRQ	Yes	Line end: This interrupt is triggered on the detection of a line-end synchronization code into the CSI2 data stream.
5	CS_IRQ	Yes	CS error: This interrupt is triggered upon detection of a mismatch between the transmitter and receiver checksums (payload).
6	FRAME_NUMBER_IRQ	Yes	Frame counter reached: This interrupt is triggered when the frame counter reaches its programmable target value.
7	LINE_NUMBER_IRQ	Yes	Line number reached: The programmable line number is received. The modulo feature can be selected ( <a href="#">CSI2_CTX_CTRL1.LINE_MODULO</a> ). When selected, the interrupt is generated for each line number multiple of the programmed line number ( <a href="#">CSI2_CTX_CTRL3.LINE_NUMBER</a> ); otherwise, the interrupt is generated only for the line number.
8	ECC_CORRECTION_IRQ	Yes	ECC was used to correct a 1-bit error (long packets only).

## 12.4 Camera ISP Functional Description

### 12.4.1 Block Diagram

Figure 12-53 is the camera ISP top-level block diagram. The camera ISP supports two simultaneous pixel flows, but only one of them can use the video-processing hardware at a time:

- Camera parallel interface (CPI) + CSIa (MIPI CSI2): CPI interface data go through the video-processing hardware. CSIa interface data go directly to memory.
- CSIa (MIPI CSI2) + CSIb (MIPI CSI1): CSIa or CSIb interface data go through the video-processing hardware. The CSI interface not using the video-processing hardware goes directly to memory.

---

**NOTE:** Due to a pin-muxing limitation, CPI and CSIb cannot be active at the same time.

CPI + CSIa: the data width is limited to 10 bits on the parallel interface.

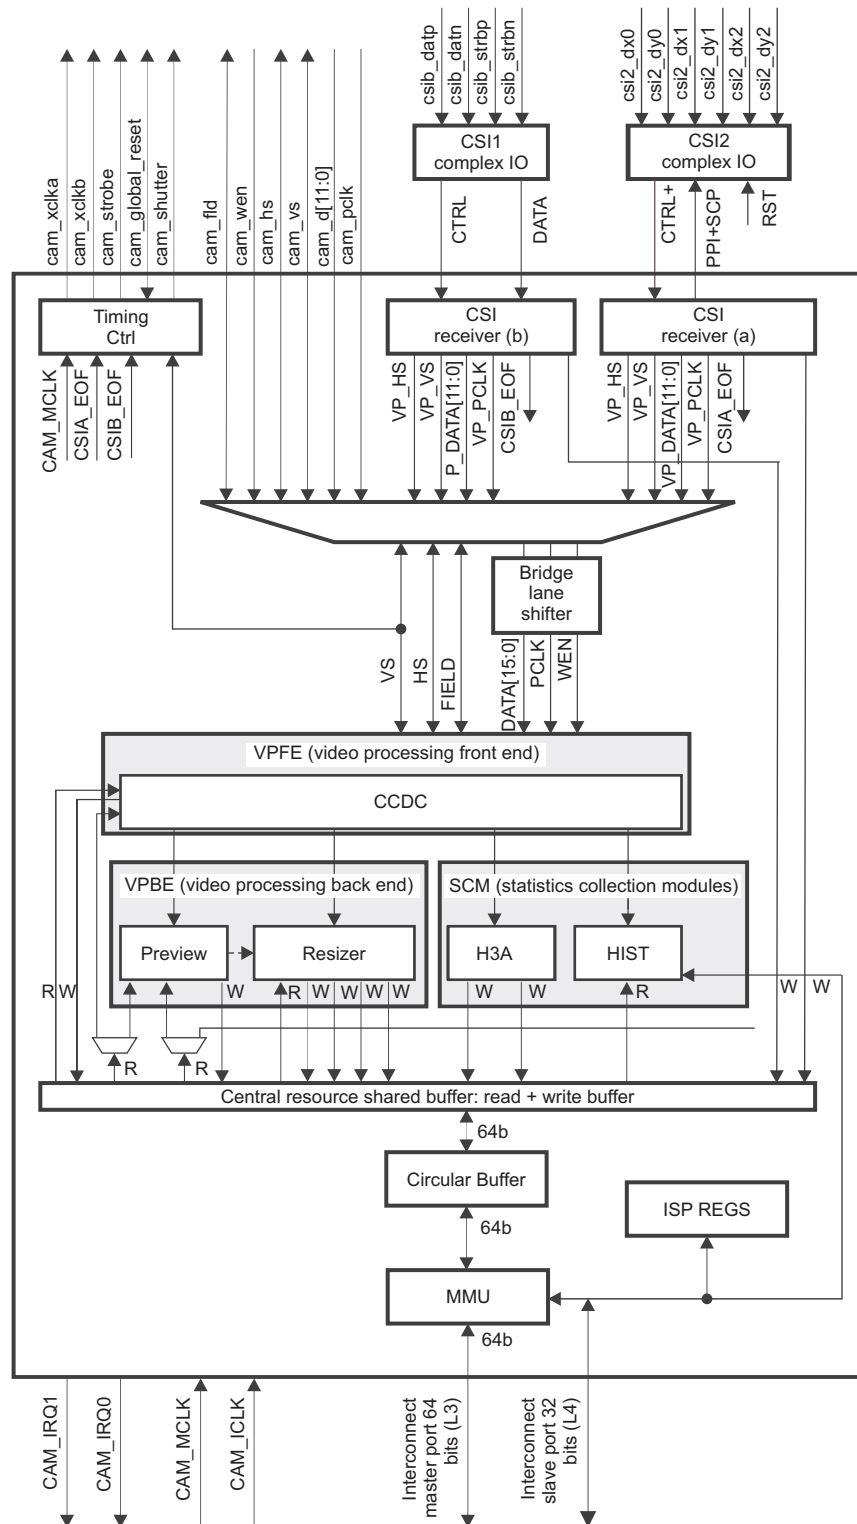

---

The camera ISP master port is connected to the L3 interconnect, and the slave port is connected to the L4 interconnect (from the camera ISP point of view, commands are output from the camera ISP to the L3 and data are input/output. From the camera ISP point of view, commands are input from the L4 to the camera ISP and data are input/output).

Figure 12-53 shows the camera ISP block diagram.

Figure 12-53. Camera ISP Block Diagram

camisp-311

The camera ISP module comprises the following blocks:

- Timing control: Includes a timing generator and a control-signal generator:
  - The timing generator allows the generation of two clocks that can be used by the external image sensors.

- The control-signal generator allows the generation of signals for strobe flash, mechanical shutter, and global reset.
- Two CSI receivers (one MIPI CSI1 and one MIPI CSI2): The CSI receiver interfaces with a serial camera through the complex I/O and transfers received data to memory or to the video pipeline.
- Bridge-lane shifter:
  - The data-lane shifter gives flexibility to the parallel camera connection and permits dynamic reduction of pixel data.
  - The bridge allows higher transfer rates when data is captured from the parallel interface and sent to memory.
- Video-processing front end (VPFE): Comprises the CCDC. This module provides the camera ISP with a powerful and flexible front end interface. It directly affects the input image data:
  - The CCDC provides an interface to image sensors and digital video sources and processes image data.
- Video-processing back end (VPBE): Comprises preview and resizer modules:
  - The preview module is a parameterized hardwired image-processing block whose image-processing functions can be customized for each sensor type to realize good image quality and video frame rates for digital still camera preview displays and video-recording modes.
  - The resizer module provides a means of sizing the input image data to the desired display or video-encoding resolution. Zoom is limited to 4x in both vertical and horizontal directions for each pass. After one (on-the-fly) upscaling pass, the image can be sent to memory and then resent through the resizer.
- Statistics-collection modules (SCM): H3A and histogram modules that provide statistics on the incoming images to help designers of camera systems:
  - The hardware 3A module supports the control loops for AF, AWB, and AE by collecting metrics about RAW image data from the CCDC.
  - The histogram module bins input color pixels, depending on the amplitude, and provide statistics required to implement various 3A (AE/AF/AWB) algorithms and tune the final image/video output. The histogram module can operate on RAW image data from CCDC or memory.
- Central-resource shared buffer logic (CRSBL): Buffers and schedules memory accesses requested by the camera modules
- Circular buffer: Avoids storage of full image frames in the memory when the data must be post and/or preprocessed by software.
- MMU: Performs virtual-to-physical address translation between its interconnect slave and interconnect master access ports

#### 12.4.1.1 Possible Data Paths Inside the Camera ISP

Data paths inside the camera ISP hardware depend on the image format sourced by the sensor (RAW RGB, YUV4:2:2, JPEG,...).

Table 12-23 lists the modules used for the different data types. The formats described in the columns are the formats at the inputs of the CCDC (after the bridge-lane shifter). It is the internal parallel format.

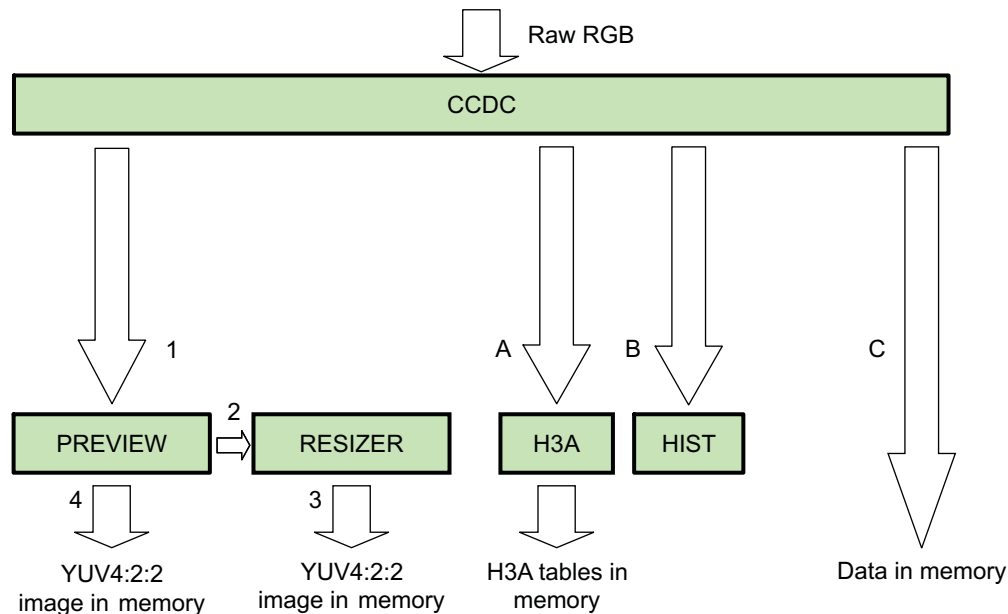

**Table 12-23. Allowed Data Flows for Hardware at the Input of the CCDC Module**

Module	6/7 Bits RAW Format	8/10 Bits RAW Format	11/12/14 Bits RAW Format	YUV4:2:2 Format	Other Formats (JPEG,RGB4:4:4,...)
CCDC	+	+	+	+	+ All formats not treated by hardware
Preview	+	+			
Resizer	+	+		+	
H3A	+ Except AF	+ Except AF for RAW8			
Histogram	+	+			

### 12.4.1.1.1 RGB RAW Data

Figure 12-54 shows the data path of images in RAW format.

**Figure 12-54. Camera ISP/Data Path/RAW RGB Images**

camisp-103

RAW data are processed through the CCDC module and are directly pipelined to the preview engine. Another way is to output directly from the CCDC to memory (C). In the preview block; the format is converted from RAW data to YUV4:2:2 (1). The data can be output to memory (4) or pipelined to the resizer (2). The rescaled YUV4:2:2 image is finally stored in memory (3).

In parallel, processed data in the CCDC are used by the H3A module (A), which writes tables of statistics in memory, and by the HIST module (B). The results of the HIST modules are stored in status registers in the HIST module.

**NOTE:**

- This data path is correct for RAW10 data.
- The data path for RAW8 data is similar to that for RAW10, except that the autofocus module in the H3A does not support RAW8.
- RAW11 data must be sent directly to memory (C).
- RAW12 data must be sent to memory (C) or pixel dynamic must be reduced RAW8 or RAW10 by the bridge-lane shifter module, before the CCDC.
- RAW14 data must be sent to memory (C) or pixel dynamic must be reduced to RAW8 or RAW10 by the bridge-lane shifter module, before the CCDC.

### 12.4.1.1.2 YUV4:2:2 Data

Figure 12-55 shows the data path of images in YUV4:2:2 format.

**Figure 12-55. Camera ISP/Data Path/YUV4:2:2 Images**

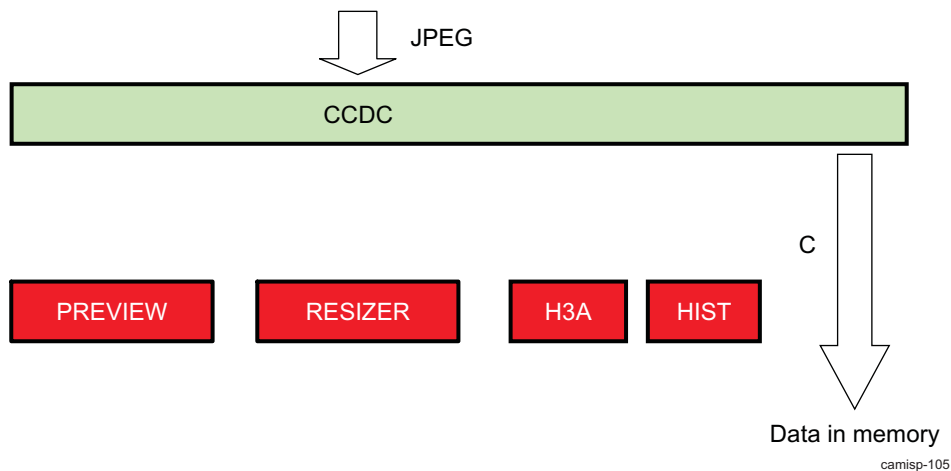

When the sensor-output format is YUV4:2:2, the CCDC block is directly pipelined to the resizer (1) or output directly to the memory (C). The rescaled YUV4:2:2 images are finally stored in memory (2).

The modules in red in [Figure 12-55](#) are not used when the format is YUV4:2:2.

### 12.4.1.1.3 JPEG Data

[Figure 12-56](#) shows the data path of images in JPEG format.

**Figure 12-56. Camera ISP/Data Path/JPEG Images**

When the sensor output format is JPEG, the CCDC block is directly output to the memory (C).

The modules in red in [Figure 12-56](#) are not used when the format is JPEG.

## 12.4.2 CSI1 Receiver

### 12.4.2.1 CSI1 Receiver Features

The CSI1 receiver features are listed below:

- Image from sensor
  - Transfer of pixels and data received by the CSI1 DSI\_PHY RX to system memory or to the video pipeline
  - Unidirectional data link

- 1D and 2D addressing mode
- False synchronization code protection
- Ping-pong mechanism for double-buffering
- Support of RGB, RAW, YUV, and JPEG formats
- Image read from memory
  - RAW formats supported

## 12.4.2.2 CSI1 Receiver Functional Description

### 12.4.2.2.1 Overview

Figure 12-57 is the CSI1 receiver top-level block diagram. The CSI1 receiver takes serial data from a CSI1-compatible image sensor, converts it to parallel data, extracts the logical channels, detects and extracts the synchronization codes, reformats the data, and outputs it through the video-port interface or the interconnect interface.

The CSI1 receiver video-port interface is connected to the video-preprocessing hardware.

**Figure 12-57. CSI1 Receiver Block Diagram**

camisp-026

### 12.4.2.2.2 Complex I/O

**NOTE:** For more information about initializing and configuring the complex I/O, see [Section 12.5.1, Programming the CSI1 or CSI2 Receiver Associated Complex I/O](#).

The CSI1 complex I/O is controlled by two other SCM registers: CONTROL.CONTROL\_CSIRXFE and CONTROL.CONTROL\_CSI:

- CONTROL.CONTROL\_CSIRXFE:
  - The CS1b interface can be reset by setting the CONTROL.CONTROL\_CSIRXFE[13] CSIB\_RESET bit to 0.
  - The CS1b differential transceiver is activated through the CONTROL.CONTROL\_CSIRXFE[12] CSIB\_PWRDNZ bit.
  - The clock polarity can be changed through the CONTROL.CONTROL\_CSIRXFE[7] CSIB\_INV bit.

A 5-bit resistor trim is implemented in the CSI complex I/O. The trim is done for the termination resistors between the csib\_datp/csib\_datn and csib\_strbp/csib\_strbn pins. The same trim-bits are used to trim both resistors. This resistor value is set by eFuse, but can be overridden through the SCM:

- CONTROL.CONTROL\_CSI:
  - The resistor trimming value set by eFuse can be read through the CONTROL.CONTROL\_CSI[25:21] CSI\_B\_TRIM\_FUSE bit field for CS1b.
  - The CONTROL.CONTROL\_CSI[31] CSI\_B\_MUX\_CTRL bit permits to override CS1b receiver trimming eFuse
  - The CONTROL.CONTROL\_CSI[20:16] CSI\_B\_TRIM\_REG bit field contains the value to replace eFuse one for CS1b
  - The CONTROL.CONTROL\_CSIRXFE[8] CSIB\_RESENABLE bit must be set to 1 to enable the CS1b internal resistor.

#### 12.4.2.2.3 Physical Layer

The CSI1 serial interface is a unidirectional differential serial interface. The physical layer of the CSI1 is based on SubLVDS signaling.

Data-clock signaling consists of two parallel signals: data and clock:

- The data signal carries bit-serial data. The CSI1 transmitter writes the data on each falling edge of the clock. The data is usually transmitted byte-wise, LSB first.
- The data clock signal carries the clock signal. The CSI1 transmitter writes the data on each falling edge of the clock. The CSI1 receiver reads the data on the rising edge of the clock.

#### 12.4.2.2.4 Protocol Layer

The CSI1 protocol layer defines how image-sensor data are transported to the physical layer.

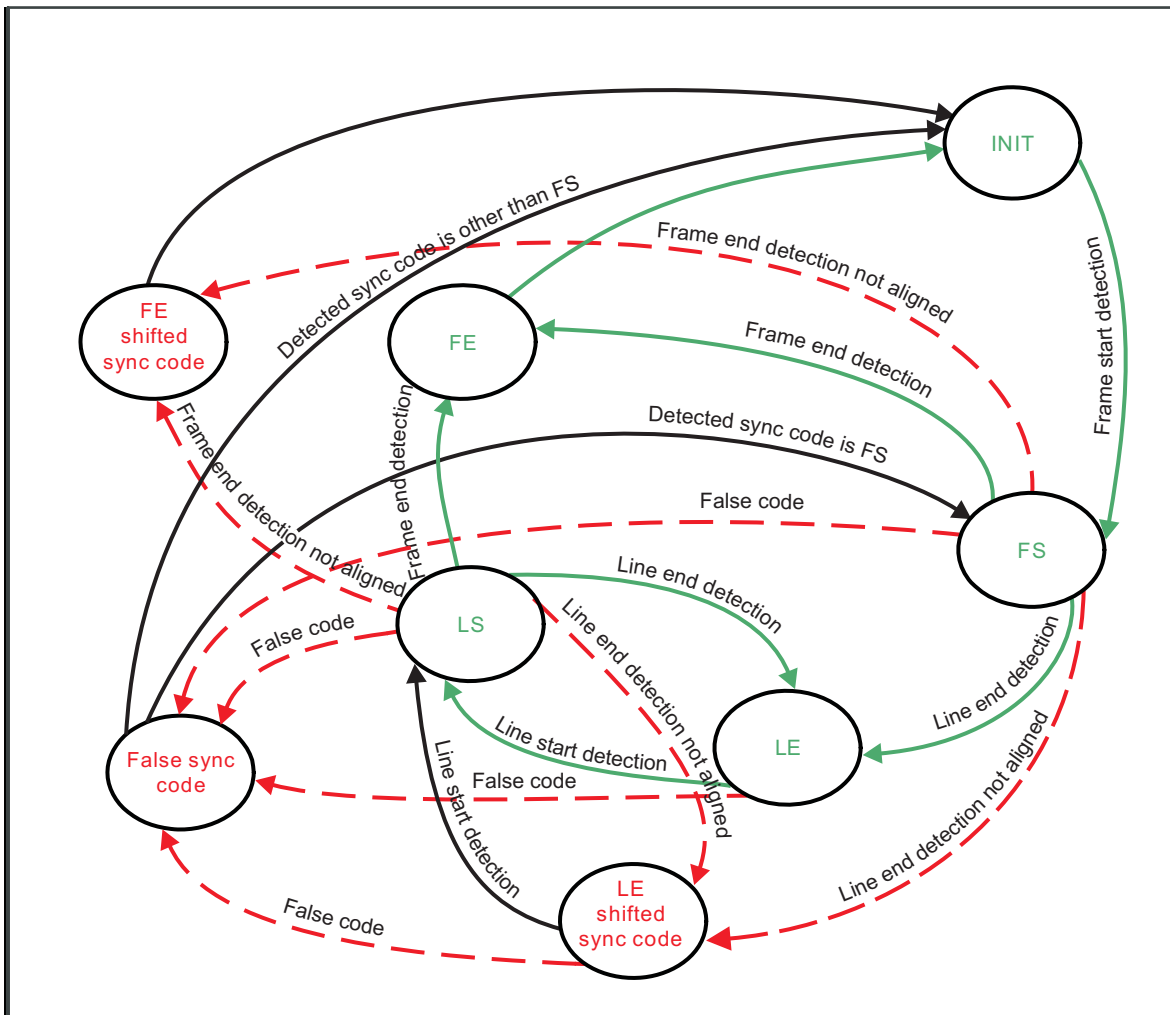

The CSI1 protocol layer transports logical channels, which are composed of frames. A frame comprises embedded data and image-sensor data. Each frame is clearly identified by unique synchronization codes: frame start, frame end, line start, and line end. Image-sensor data can have multiple data types (select the data type in the CSI1\_CTRL1 [7:3] FORMAT bit field). For details about data types, synchronization code, and FSP encoding/decoding, see [Section 12.2.4.4](#).

##### 12.4.2.2.4.1 Synchronization Finite State-Machine

[Figure 12-58](#) shows the CSI1 receiver finite state-machine (FSM). The CSI1 receiver synchronization operates bitwise.

The expected synchronization code order is FSC, LEC, LSC, and LEC...etc., LSC, LEC, LSC, FEC for all data types except JPEG8. For JPEG8, the expected synchronization code order is FSC, FEC.

If the synchronization code order is not respected, the state-machine goes to FalseSyncCode state. Because line length is always a multiple of 32 bits, the LEC and FEC codes are always aligned on a 32-bit boundary. If LEC or FEC is not aligned on a 32-bit boundary, the state-machine goes to LShiftedSyncCode or FShiftedSyncCode state. [Figure 12-58](#) shows the synchronization state-machine.

**Figure 12-58. Synchronization State-Machine**

camisp-194

In case of synchronization code errors, the CSI1 receiver can reinitialize itself. No software intervention is required for most synchronization-code errors:

- **Line-end shifted code:** The receiver either removes the additional bits or adds dummy bits. The next LS synchronization code resynchronizes the state-machine to normal behavior. A shifted line-end (LE) synchronization code triggers an LE\_IRQ event.
- **Frame-end shifted code:** The receiver either removes the additional bits or adds dummy bits. The next FS synchronization code resynchronizes the state-machine to normal behavior. A shifted frame-end (FE) synchronization code triggers an FE\_IRQ event.
- **False synchronization code:** The current frame is lost. The receiver stops acquiring data, flushes its internal FIFO, and asserts the FSC\_IRQ event. The next FS synchronization code resynchronizes the state-machine to normal behavior.

#### 12.4.2.2.4.1.1 Frames

##### Structure

Figure 12-59 shows the generic (non-JPEG) description of a CSI1 frame with synchronization codes. Each CSI1 frame line is composed of a finite number of 32-bit words.

**Figure 12-59. CSI1 Frame Structure: Non-JPEG Data Format**

camisp-028

The period between LEC and new is called the line-blanking period. The time between FEC and new FSC is called the frame-blanking period. The CSI1 receiver works with line-blanking periods set to 0 or longer.

Figure 12-60 shows CSI1 frame structure for the JPEG8 case. The JPEG stream is composed of a finite number of 32-bit words. LSC and LEC synchronization codes are never used when the CSI1 interface transports a JPEG bitstream; only FSC and FEC synchronization codes are used.

**Figure 12-60. Frame Structure: JPEG8 Data Format**

camisp-196

**Data**

A frame comprises embedded data and image-sensor data. Figure 12-61 shows the location of embedded data and image-sensor data in the frame. The following definitions apply:

- 0 or more start-of-frame (SOF) status lines can be embedded at the beginning of a CSI1 frame.
- Image data comprises pixels of the same data formats. It may contain visible or nonvisible pixels.
- 0 or more end-of-frame (EOF) status line(s) can be embedded at the end of a CSI1 frame.
- SOF lines, pixel data, and EOF lines do not overlap.

The CSI1 receiver does not use the information contained in the status lines. However, it extracts it and stores it in memory for use by the software. Figure 12-61 shows the CSI1 data structure.

**Figure 12-61. CSI1 Data Structure**

FSC	Embedded data - SOF line(s)	LEC	CRC+pad	Line blanking
LSC		LEC	CRC+pad	
LSC		LEC	CRC+pad	
LSC		LEC	CRC+pad	
LSC	Pixel data	LEC	CRC+pad	
LSC		LEC	CRC+pad	
[...]		[...]	[...]	
LSC		LEC	CRC+pad	
LSC		LEC	CRC+pad	
LSC		LEC	CRC+pad	
LSC		LEC	CRC+pad	
LSC		LEC	CRC+pad

LSC	Embedded data - EOF line(s)	LEC	CRC+pad	
LSC		LEC	CRC+pad	
LSC		FEC	CRC+pad	
Frame blanking				

camisp-197

Embedded information (SOF and EOF lines):

- Embedded information is never compressed .
- Embedded information covers full lines.
- Embedded information is not encoded in the same data format as pixel data. The CSI1 receiver extracts embedded information, but does not modify the data format.
- False-synchronization-code protection is implemented; the receiver ensures that the embedded data contains no synchronization codes.

Pixel data:

- Pixel data can be compressed.
- Pixel data comprises pixels of the same data format.
- False-synchronization-code protection is implemented; the receiver ensures that the pixel data contains no synchronization codes.

#### 12.4.2.2.5 Memory Read Channel

The memory channel can perform the following operations:

- Reads data from memory. It is unpacked if necessary.
- Can send the data to the video pipeline
- Can send the data back to memory. It can be packed before it is sent to memory.

It cannot receive its input data directly from the sensor, and the logical channels are disabled when the memory channel is enabled.

#### **12.4.2.2.5.1 Video Port**

The video port always receives unpacked data. It can be enabled using the CSI1\_LCM\_CTRL [2] DST\_PORT register. Its clock can be selected with the CSI1\_CTRL [9:8] VP\_OUT\_CTRL register.

The data format used by the video port is defined by the CSI1\_LCM\_CTRL [26:24] DST\_FORMAT register.

#### **12.4.2.2.5.2 Encode, Pack, and Store Data**

This stage is used only when data are sent to memory. Memory destination is selected using the CSI1\_LCM\_CTRL [2] DST\_PORT register. The output data format is defined by the CSI1\_LCM\_CTRL [26:24] DST\_FORMAT, and CSI1\_LCM\_CTRL [31] DST\_PACK registers.

The destination address and offset for the output data of the memory channel are set by the CSI1\_LCM\_DST\_ADDR and CSI1\_LCM\_DST\_OFST registers.

### 12.4.3 CSI2 Receiver

#### 12.4.3.1 CSI2 Receiver Features

The CSI2 receiver module is a master on the L3 interconnect for storing data in memory and a slave on the L4 interconnect for register access.

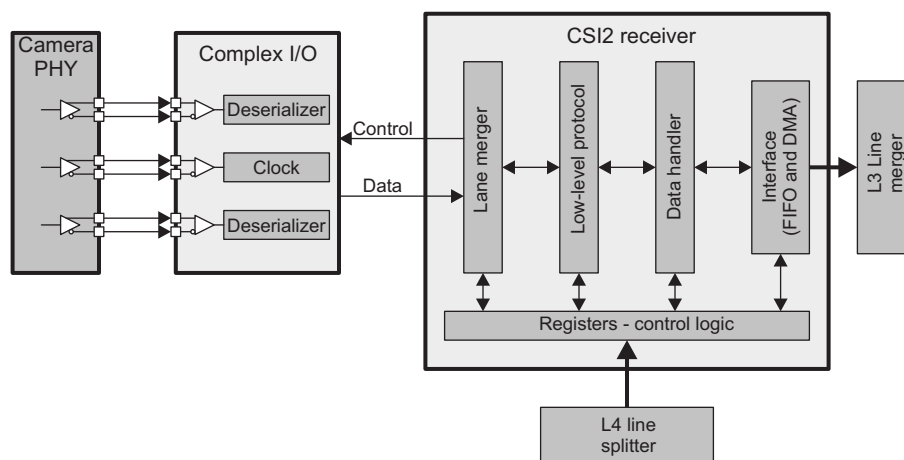

The main features of the CSI2 receiver module are:

- Transfer pixels and data received by the CSI2 complex I/O to the system memory
- Unidirectional data link
- Minimum of one and maximum of two configurable data links in addition to clock signaling
- Maximum data rate of 800M bps per data pair
- Data merger for 2-data lane configuration
- Error detection and correction by the protocol engine
- DMA engine integrated with dedicated FIFO
- 1D and 2D addressing modes
- Up to eight contexts to support eight dedicated configurations of virtual channel ID and data types
- Ping-pong mechanism for double-buffering
- JPEG support for unknown length transfer (no extraction of the thumbnail)
- All primary and secondary MIPI-defined formats are supported (RGB, RAW, and YUV)
- Storage in progressive mode for interlaced stream (using line numbering)
- Configuration of the complex I/O
- Fully configurable interface of the complex I/O: position of the clock and data and order of +/- differential signals for each pair

#### 12.4.3.2 CSI2 Receiver Block Diagram

Figure 12-62 is the block diagram of the CSI2 receiver connected to the complex I/O.

**Figure 12-62. CSI2 Receiver Block Diagram**

camisp-238

#### 12.4.3.3 Physical Layer Lane Configuration

The CSI2 serial interface is a unidirectional differential serial interface with data/clock for the physical layer. The CSI2 PHY is based on the MIPI DSI\_PHY Specification version 0.89.

The maximum CSI2 receiver data transfer capacity is 800M bps per data lane.

Data-clock signaling consists of four to six signals: one or two data lanes and one clock lane:

- The data signal carries the bit-serial data. The CSI2 transmitter in the image sensor sends the data in quadrature with the DDR clock in HS mode; otherwise, the clock is extracted from the received data in LS mode. Data is transmitted byte-wise, LSB first. The CSI2 complex I/O receives the data and sends the byte stream to the CSI2 receiver.
- The clock signal carries the DDR clock signal.

Each physical lane can be a data or a clock lane. The clock/data lane must be configured before transmission to indicate the byte order while merging the received bytes into a byte stream.

Lanes are configured through the [CSI2\\_COMPLEXIO\\_CFG1](#) register. The `CLOCK_POSITION` and `CLOCK_POL` fields configure which lane transmits the clock and define its polarity. Four fields (`DATA1_POSITION`, `DATA1_POL`, `DATA2_POSITION`, and `DATA2_POL`) configure the data lanes and their polarity. The `DATA2_POSITION` field can be set to 0; in this case, only the data lane defined in the `DATA1_POSITION` field is used, and data is transmitted on only one clock lane and one data lane.

The [CSI2\\_COMPLEXIO\\_CFG1](#) register also contains a bit field affecting complex I/O power management.

---

**NOTE:** For more information about initializing and configuring the signals along with the complex I/Os, see [Section 12.5.1, Programming the CSI1 or CSI2 Receiver Associated Complex I/O](#).

---

#### 12.4.3.4 ECC and Checksum Generation

The CSI2 receiver includes an ECC in the packet header and a checksum in the packet footer for long-packet transmission. These two fields can be used to detect and/or correct errors in the received packet.

##### 12.4.3.4.1 ECC

To detect and correct transmission errors of the header of short and long packets, an 8-bit ECC is included in the header of packets (short and long packet).

The ECC concerns all the fields for a short packet (data ID and short-packet data field) and the packet header for long packet (data ID and word count). The ECC can only correct one error. Additional errors cannot be repaired, but they are flagged.

The CSI2 receiver ECC is compared against the CSI2 transmitter ECC embedded in the bit stream. If the ECC does not match, an interrupt is triggered to the host CPU.

For both long and short packets, the correction is always done if there is only one error per packet.

An ECC error with or without correction can be reported at two levels, depending on the type of packet. [Table 12-24](#) describes the field where events are logged. Logging cannot be disabled, but users can set the corresponding bit in the [CSI2\\_IRQENABLE](#) and [CSI2\\_CTX\\_IRQENABLE](#) registers to prevent event generation at a higher level.

**Table 12-24. ECC Event Logging**

	Short Packet	Long Packet
With correction	Global <a href="#">CSI2_IRQSTATUS</a> [12] <code>ECC_CORRECTION_IRQ</code>	Context <a href="#">CSI2_CTX_IRQSTATUS</a> [8] <code>ECC_CORRECTION_IRQ</code>
Without correction	Global <a href="#">CSI2_IRQSTATUS</a> [11] <code>ECC_NO_CORRECTION_IRQ</code>	Global <a href="#">CSI2_IRQSTATUS</a> [11] <code>ECC_NO_CORRECTION_IRQ</code>

The ECC check can be disabled (short and long packet) by writing 0 in the [CSI2\\_CTRL](#)[2] `ECC_EN` bit field. Writing 1 enables the ECC check.

##### 12.4.3.4.2 Checksum

To detect errors in transmission of the payload of long packets, a 16-bit CRC checksum is computed on the payload of the long packets in the transmitter. This CRC is stored in the packet footer. A CRC is also computed in the CSI2 receiver. If the checksums do not match, an event is triggered to the host CPU.

CRC errors are logged in the CS\_IRQ field of the corresponding context register, [CSI2\\_CTx\\_IRQSTATUS](#). Logging cannot be disabled, but users can set the corresponding bit in the [CSI2\\_CTx\\_IRQENABLE](#) register to prevent event generation at a higher level.

The CRC check can be disabled for a specific context by writing 0 in the [CSI2\\_CTx\\_CTRL1\[5\]](#) CS\_EN bit. Writing 1 enables the CRC check.

### 12.4.3.5 Short Packet

There are two types of short packets in the CSI2 receiver:

- Synchronization short packet: Used by the protocol engine to synchronize frame and line (data ID from 0x0 to 0x7)
- Generic short packet: User-dependent; not treated by the protocol engine (data ID from 0x8 to 0xF)

When a generic short packet is received by the CSI2 receiver, the ECC check is performed if it is enabled (see [Section 12.4.3.4.1, ECC](#)). Then, the short packet is written in the [CSI2\\_SHORT\\_PACKET\[23:0\]](#) SHORT\_PACKET bit field. The ECC field is deleted from the short packet. [Figure 12-63](#) shows the SHORT\_PACKET field format.

**Figure 12-63. SHORT\_PACKET Field Format**

An event is logged when a short packet is stored in the SHORT\_PACKET\_IRQ bit in the [CSI2\\_IRQSTATUS\[13\]](#) register. Logging cannot be disabled, but users can set the corresponding bit in the [CSI2\\_IRQENABLE](#) register to prevent event generation at a higher level.

The application reads the [CSI2\\_SHORT\\_PACKET](#) register before the next short packet with a code between 0x8 and 0xF. There is a single register for capturing the generic short packet, because no data type in it is associated with context.

### 12.4.3.6 Virtual Channel and Context

The CSI2 protocol layer transports virtual channels. The purpose of virtual channels is to separate different data flows interleaved in the same data stream. Each virtual channel is identified by a unique channel identification number in the packet header. This channel identification number is encoded in the 2-bit code.

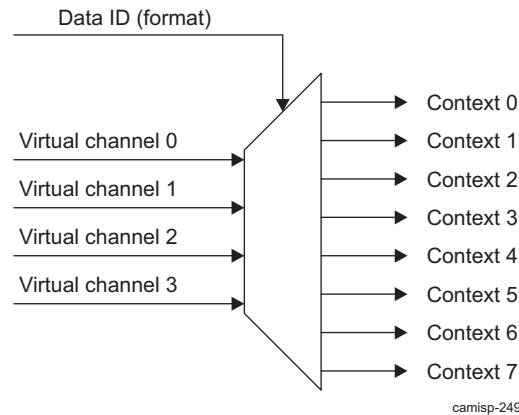

The CSI2 receiver monitors the channel identifier number and demultiplexes the interleaved data streams. The CSI2 receiver supports up to four concurrent virtual channels.

The CSI2 receiver supports eight contexts to control the four possible virtual channels and the different data transmitted through them. A context is linked to a specific data type transported by a given virtual channel. The following two bit fields permit configuration of a context:

- [CSI2\\_CTx\\_CTRL2\[12:11\]](#) VIRTUAL\_ID: Configures the virtual ID linked to the current context
- [CSI2\\_CTx\\_CTRL2\[9:0\]](#) FORMAT: Configures the data format linked to the current context

[Figure 12-64](#) shows the relationships between virtual channels and contexts.

**Figure 12-64. Virtual Channel to Context**

Each context consists of eight registers: six registers to control the corresponding context and two to log and enable events from the context. All registers in a context can be modified at any time; however, modifications apply only from the start of the following frame.

A context can be enabled independently by writing 1 in the [CSI2\\_CT<sub>x</sub>\\_CTRL1\[0\]](#) CTX\_EN bit field; writing 0 disables the corresponding context.

When acquiring frames on a context, users can write the number of frames to capture in the [CSI2\\_CT<sub>x</sub>\\_CTRL1\[15:8\]](#) COUNT bit field. Acceptable values are 0:255; 0 stands for infinite capture (no count). After each frame acquired, the count value is decremented by 1. When the count value reaches 0, the [CSI2\\_CT<sub>x</sub>\\_IRQSTATUS\[6\]](#) FRAME\_NUMBER\_IRQ event is set and the CTX\_EN bit is set to 0. To write a value in the COUNT bit field, the [CSI2\\_CT<sub>x</sub>\\_CTRL1\[4\]](#) COUNT\_UNLOCK bit must be set to 1. If the COUNT\_UNLOCK value is 0, a write in the COUNT bit field has no effect.

The [CSI2\\_CT<sub>x</sub>\\_CTRL3\[15:0\]](#) LINE\_NUMBER bit field configures the generation of the [CSI2\\_CT<sub>x</sub>\\_IRQSTATUS\[7\]](#) LINE\_NUMBER\_IRQ event. The [CSI2\\_CT<sub>x</sub>\\_CTRL1\[1\]](#) LINE\_MODULO bit configures how the LINE\_NUMBER event is generated:

- 0: The event is generated one time by frame.
- 1: The event is generated modulo LINE\_NUMBER (the event can be generated more than once in a frame).

During a frame capture, the [CSI2\\_CT<sub>x</sub>\\_CTRL2\[31:16\]](#) FRAME\_NUMBER bit field shows the number that identifies the frame received.

### 12.4.3.7 DMA Engine

The CSI2 receiver integrates its own DMA engine with dedicated FIFO.

Global DMA configuration (single access, non-streaming and posted writes) is common to the eight channels and is defined in the [CSI2\\_CTRL](#) register. Configuration of the ping-pong address and the offset between lines is specific for a given context; therefore, each context has its own DMA configuration registers.

The DMA engine supports the following requests:

- Single write

When an element (the size depends on the data type) is present in the FIFO, the DMA engine initiates a single write.

All single requests sent to the interconnect are back-to-back requests with no idle, if the FIFO has enough data to supply the DMA.

The DMA starts to write in memory using the [CSI2\\_CT<sub>x</sub>\\_DAT\\_PING\\_ADDR\[31:5\]](#) ADDR bit field for the first frame to be transferred and then uses the [CSI2\\_CT<sub>x</sub>\\_DAT\\_PONG\\_ADDR\[31:5\]](#) ADDR bit field and the ping address alternately. So, the first frame uses the ping address, the second frame uses the pong address, the third frame uses the ping address, and so on.

The `CSI2_CTX_CTRL1[3]` PING\_PONG status bit indicates whether the ping address (`CSI2_CTX_DAT_PING_ADDR`) or the pong address (`CSI2_CTX_DAT_PONG_ADDR`) was used to store the pixel data of the last frame. After reset or after a 0-to-1 edge transition in the `CSI2_CTRL[0]` IF\_EN register, the pixel data is written in the ping buffer and `CSI2_CTX_CTRL1[3]` PING\_PONG = PONG. When the number of FECs received equals the value programmed in the `SI2_CTX_CTRL1[23:16]` FEC\_NUMBER bit field, the pixel data are written in the pong buffer and `CSI2_CTX_CTRL1[3]` PING\_PONG = PING. `CSI2_CTX_CTRL1[3]` PING\_PONG toggles after the `CSI2_CTX_CTRL1[23:16]` FEC\_NUMBER FEC sync code with the virtual channel ID defined is received in the `CSI2_CTX_CTRL2[12:11]` VIRTUAL\_ID bit field.

The `CSI2_CTX_CTRL1[23:16]` FEC\_NUMBER bit field must be set as follows:

- In progressive mode, set to 1.
- In interlaced mode, set to the number of interlaced frames to recreate a progressive image in the PING\_PONG buffer.

#### 12.4.3.7.1 Progressive Frame to Progressive Storage

After each line, a new start line address is computed, depending on the value of the `CSI2_CTX_DAT_OFST[15:5]` OFST bit field:

- If OFST = 0, the new line starts immediately after the last pixel (data are written contiguously in memory).
- Otherwise, the OFST value sets the offset between the first pixel of the previous line and the first pixel of the current line in memory.

For the ping frame:

```
@Line0 = CSI2_CTX_DAT_PING_ADDR @Line1 = @Line0 + CSI2_CTX_DAT_OFST
```

```
@Line2 = @Line1 + CSI2_CTX_DAT_OFST
```

For the pong frame:

```
@Line0 = CSI2_CTX_DAT_PONG_ADDR @Line1 = @Line0 + CSI2_CTX_DAT_OFST
```

```
@Line2 = @Line1 + CSI2_CTX_DAT_OFST
```

#### 12.4.3.7.2 Interlaced Frame to Progressive Storage

The mode is functional only when the line numbers are transmitted. It is automatically enabled without setting.

For the ping frame:

```
@LineX = CSI2_CTX_DAT_PING_ADDR + CSI2_CTX_DAT_OFST * Line_Number
```

For the pong frame:

```
@LineX = CSI2_CTX_DAT_PONG_ADDR + CSI2_CTX_DAT_OFST * Line_Number
```

Figure 12-65 shows how data are stored in memory regarding DMA configuration.

**Figure 12-65. Pixel Data Destination Setting in Progressive and Interlaced Mode**

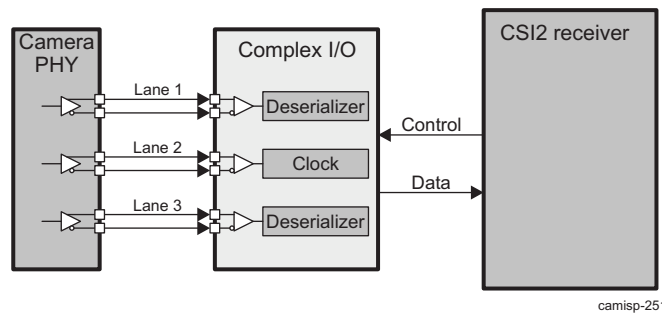

camisp-250

### 12.4.3.8 Complex I/O

The complex I/O is the interface between the CSI2 transmitter (camera sensor) and the CSI2 receiver. This module transforms the bit stream divided into one or two serial data lanes into a bit stream compatible with the CSI2 receiver and one clock lane. Figure 12-66 shows the CSI2 receiver.

**Figure 12-66. Complex I/O Overview**

camisp-251

The [CSI2\\_COMPLEXIO1\\_IRQSTATUS](#) register logs complex I/O events of the following types:

- Line power state change (all lanes in ULP, at least one lane exits ULP, etc.)
- Error on one lane

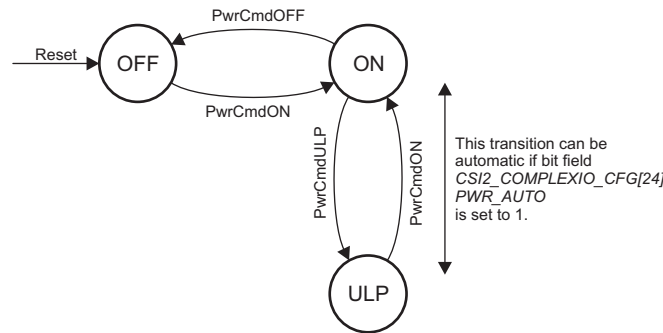

The CSI2 receiver embeds two registers to configure/read some complex I/O parameters:

- The [CSI2PHY\\_CFG0](#) register detects clock miss with respect to the MIPI specification and control timing.
- The [CSI2PHY\\_CFG1](#) register reports completion of reset on the different parts of the module and configures timing parameters.

The complex I/O has three power modes: on, off, and ULP (ultra-low power). These modes can reflect the ON or ULP power state of the three differential lines if the [CSI2\\_COMPLEXIO\\_CFG1\[24\]](#) PWR\_AUTO bit is set to 1. If the PWR\_AUTO bit is at reset value (0), the complex I/O power state is controlled by the [CSI2\\_COMPLEXIO\\_CFG1\[28:27\]](#) PWR\_CMD bit field, which directly defines the power state. Figure 12-67 shows the complex I/O power finite state machine (FSM).

Figure 12-67. Complex I/O Power FSM

camisp-253

Another register, [CSI2\\_TIMING](#), is used to control the power state of the complex I/O module with regards to the differential line state. This register is used to control the mode of the complex I/O (RxMode or NoRxMode) and the delay between all the differential lines on STOP state and complex I/O on NoRxMode. The [CSI2\\_TIMING](#)[15] FORCE\_RX\_MODE\_IO1 bit field sets the complex I/O in RxMode or in NoRxMode (stopped mode). The FORCE\_RX\_MODE\_IO1 bit is automatically reset to 0 by hardware when the counter ends and the FSM returns to NoRxMode. Three bit fields ([CSI2\\_TIMING](#)[14] STOP\_STATE\_X16\_IO1, [CSI2\\_TIMING](#)[13] STOP\_STATE\_X4\_IO1, and [CSI2\\_TIMING](#)[12:0] STOP\_STATE\_COUNTER\_IO1) configure the delay between line stop mode and complex I/O stop mode. The delay represents the number of functional clock (CAM\_FCLK) cycles and can be calculated as follows:

$$\text{Total delay in CAM\_FCLK cycle} = \text{CSI2\_TIMING.STOP\_STATE\_COUNTER\_IO1} \times (1 + \text{CSI2\_TIMING.STOP\_STATE\_X16\_IO1} \times 15) \times (1 + \text{CSI2\_TIMING.STOP\_STATE\_X4\_IO1} \times 3).$$

Table 12-25 lists the possible values of the delay, in terms of the CAM\_FCLK cycles, depending on the values of the STOP\_STATE\_X16\_IO1 and STOP\_STATE\_X4\_IO1 bits.

Table 12-25. Possible Time-Out Value for RxMode Counter

STOP_STATE_X16_IO1	STOP_STATE_X4_IO1	Possible Delay Value (In Functional Clock Cycles)
0x0	0x0	8191 (with step of 1)
0x0	0x1	32764 (with step of 4)
0x1	0x0	131056 (with step of 16)
0x1	0x1	524224 (with step of 64)

The state-machine controlling the RxMode is presented in Figure 12-68.

Figure 12-68. RxMode and StopState FSM

camisp-254

## 12.4.4 Timing Control

### 12.4.4.1 Timing-Control Features

The timing-control module provides two clocks (cam\_xclka and cam\_xclkb) that can be used by external camera modules. It also generates the control signals (cam\_strobe and cam\_shutter) for the flash prestrobe, flash strobe, and mechanical shutters.

The timing-control module includes a timing generator and a control-signal generator.

### 12.4.4.2 Timing Control

Figure 12-69 shows a block diagram of the timing-control module.

Figure 12-69. Timing-Control Module

camisp-102

#### 12.4.4.2.1 Timing Generator

The timing generator generates the cam\_xclka and cam\_xclkb clocks based on the CAM\_MCLK frequency, which can be up to 216 MHz. The cam\_mclk is used only by the clock generator; the cam\_xclka and cam\_xclkb clocks are not used internally by the camera ISP. The clock divider is programmable.

The possible frequencies of cam\_xclka and cam\_xclkb and their respective configurations are described in Section 12.3.1.1.3, *Clock Configuration*.

Table 12-26 summarizes the possible frequencies as a function of the divisor values.

#### 12.4.4.2.2 Control-Signal Generator

The control-signal generator generates the prestrobe, strobe, and shutter signals: cam\_strobe and cam\_shutter. Figure 12-70 shows the principle of control-signal generation.

Figure 12-70. Control-Signal Generation

camisp-033

The control-signal generator gathers precise timings for the cam\_strobe and cam\_shutter signals, to assert and deassert the signals at known times. The timing-control-signal generator can be synchronized either on the vertical synchronization signal coming from the CS1a (VP\_VS from CS1a), CS1b (VP\_VS from CS1b), or PARALLEL interface (cam\_vs), or on an externally-generated cam\_global\_reset signal.

A multiplexer controls which of the CS1a, CS1b, or PARALLEL interface drives control-signal generation. This multiplexer can also select the externally-generated cam\_global\_reset signal as the trigger event. The **TCTRL\_CTRL** [31] GRESETDIR register defines the direction of the cam\_global\_reset signal.

- The external generated cam\_global\_reset is used as a trigger when **TCTRL\_CTRL** [31] GRESETDIR = 0 and **TCTRL\_CTRL**[27:28] INSEL = 3.
- The internally generated cam\_global\_reset is used as a trigger when **TCTRL\_CTRL** [31] GRESETDIR = 1 and **TCTRL\_CTRL**[27:28] INSEL = 3.
- If the PARALLEL interface is selected, control-signal generation works for both ITU and SYNC modes and on both output ports: video port and shared-buffer-logic (SBL) port.
- If the CS1a or CS1b interface is selected, control-signal generation works on both output ports: video port and interconnect port.

The cam\_global\_reset signal can also be generated internally by the control-signal generator under software control. In this case, the prestrobe and shutter signals are synchronized on the internally generated cam\_global\_reset signal. The multiplexer controls whether control-signal generation must be triggered by the internal or external cam\_global\_reset signal.

The prestrobe-, strobe-, and shutter-control signals can be individually enabled at any time. These signals must not be disabled by software.

The clock divider generates the CNTCLK clock based on the cam\_mclk clock. The clock divider is programmable. [Table 12-26](#) summarizes the possible frequencies as a function of the divisor values.

**Table 12-26. Control-Signal Generator: CNTCLK Frequencies**

Divisor Value <b>TCTRL_CTRL</b> [18:10] DIVC	CNTCLK Clock
0 (default)	Clock gated. No clock.
1	216 MHz, free-running.
2	108 MHz
3	72 MHz
4	54 MHz
...	...
510	0.424 MHz
511	0.423 MHz

There are three counters per control signal, for a total of nine counters. Each counter is programmable.

- The frame counter is decreased each time a full new frame is received, based on the EOF events from the CCD or CSI receiver modules.
  - A new frame is detected in the CSI RECEIVER modules on detection of a frame-start code (FSC) followed by a frame-end code (FEC).
  - A new frame is detected in the CCD module by using the falling edge of the vertical synchronization signal at the input of the CCD module.

---

**NOTE:** The rising edge of the vertical synchronization signal and the vertical synchronization polarity settings inside the CCD cannot be used. The modules have no effect on this detection.

---

- The frame counter determines how many whole frames must be ignored before the delay counter is triggered. The frame counters can be set to 0 to bypass them.
- The delay counter determines the control-signal activation delay. The counter is decreased at every CNTCLK clock cycle. When the counter reaches 0, the control signal is asserted. If the delay counter is set to 0, the control signal is asserted immediately.
- The activation-length counter determines the control-signal assertion length. The counter is decreased at every CNTCLK clock cycle. When the counter reaches 0, the signal is deasserted and the control-signal enable bit is disabled. If the activation length is set to 0, the control signal is not asserted and the control-signal enable bit is disabled.

The polarity of the following signals can be individually selected:

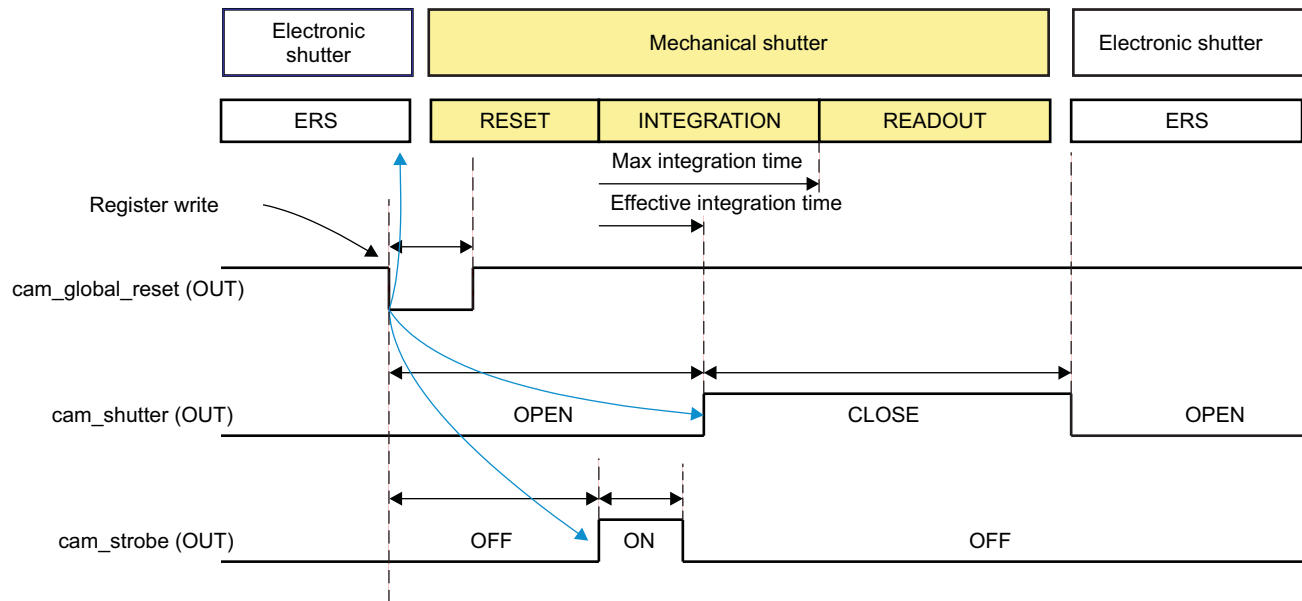

- **TCTRL\_CTRL** [26] STRBPSTRBPOL for the prestrobe and strobe signals
- **TCTRL\_CTRL** [24] SHUTPOL for the shutter signal
- **TCTRL\_CTRL** [30] GRESETPOL for the cam\_global\_reset signal

The software can trigger the generation of the cam\_global\_reset signal to the camera module. The signal-activation length is programmable. The counter is decreased at every CNTCLK clock cycle. When the counter reaches 0, the signal is deasserted and the global reset enable bit is disabled (**TCTRL\_CTRL** [29] GRESETEN bit). If the activation length is set to 0, the control signal is not asserted and the control-signal enable bit is disabled. The polarity of the cam\_global\_reset signal can be selected (**TCTRL\_CTRL** [30] GRESETPOL bit).

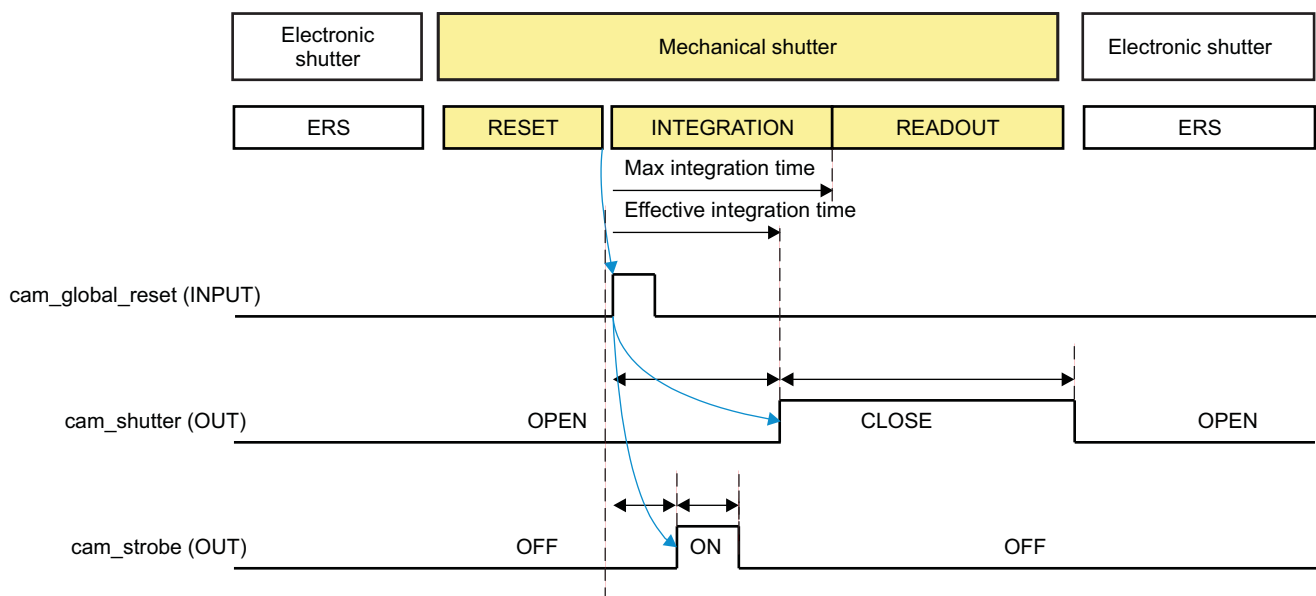

[Figure 12-71](#) shows the use of the cam\_global\_reset signal set as an input or output signal. cam\_global\_reset is asynchronous, edge-sensitive, and asserted for at least one interconnect clock cycle

**Figure 12-71. Use of cam\_global\_reset With Global Reset Release Camera Modules**

A. cam\_global\_reset is set as a camera ISP output signal

B. cam\_global\_reset is set as a camera ISP input signal

camisp-034

There are two types of shutter mechanisms: mechanical and electronic. A mechanical shutter is used only for high-resolution sensors. The three control signals (cam\_global\_reset, cam\_shutter, and cam\_strobe) are useful with a mechanical shutter. High frame rates can be achieved only with an electronic shutter. When an electronic shutter is used, none of the three control signals is used.

Mechanical shutter mechanism:

- **Reset:** All pixels of the sensor are reset to their black value. When the sensor has a global reset feature, the mechanical shutter can be open during reset.
- **Integration:** The light received by the sensor is transformed into electrical charges that are stored

inside pixels. At the end of the integration time, the shutter must be closed. Exposure time is defined by the time between reset release and shutter close.

- Readout: The charges accumulated in pixels are converted to digital values that are sent to the camera receiver.

Electronic rolling shutter mechanism (ERS):

- Each line of the sensor is reset separately and read after a fixed amount of time. Expose time is defined by the time between reset and read.

### 12.4.5 Bridge-Lane Shifter

The bridge-lane shifter module contains a data-lane shifter and an optional bridge:

- The data-lane shifter routes data sent to physical pins to the proper inputs of the CCDC module. It is controlled by the `ISP_CTRL` [7:6] SHIFT register. [Table 12-27](#) describes the different configurations.

**Table 12-27. Data-Lane Shifter**

Sensor	Connected to	Data Lane Shifter 0	Data Lane Shifter 1	Data Lane Shifter 2	Data Lane Shifter 3	Note
8 bits	[7:0]	8 bits	6 bits	4 bits	2 bits	
	[9:2]	10 bits	8 bits	6 bits	4 bits	
	[11:4]	12 bits	10 bits	8 bits	6 bits	
	[13:6]	14 bits	12 bits	10 bits	8 bits	CSI2 only
10 bits	[9:0]	10 bits	8 bits	6 bits	4 bits	
	[11:2]	12 bits	10 bits	8 bits	6 bits	
	[13:4]	14 bits	12 bits	10 bits	8 bits	CSI2 only
12 bits	[11:0]	12 bits	10 bits	8 bits	6 bits	
	[13:2]	14 bits	12 bits	10 bits	8 bits	CSI2 only
14 bits	[13:0]	14 bits	12 bits	10 bits	8 bits	CSI2 only

Blue shading means that the data is too wide for the image pipeline: use IVA2.2.

Green shading means that precision is increased for intermediate results.

Orange shading means that precision is reduced.

Unshaded cells imply normal precision.

- An optional bridge allows the packing of bytes into 16-bit words. When it is used, the maximum data rate allowed is increased. The placement of 8-bit data inside 16-bit words is configurable through the `ISP_CTRL` [3:2] PAR\_BRIDGE register. This mode can be useful to transfer an YCbCr data stream or compressed stream to memory at very high speed:
  - A minimum line-blanking period of 2 pixels must be obeyed when the bridge is enabled.
  - Some CCDC modules cannot work with the bridge. For details, see [Table 12-28](#).

### 12.4.6 Video-Processing Front End

The video-processing front end (VPFE) comprises the CCDC and the lens-shading compensation.

#### 12.4.6.1 CCDC

##### 12.4.6.1.1 CCDC Features

The CCDC is responsible for accepting RAW (unprocessed) image/video data from a sensor. It can also accept YUV video data in numerous formats. For RAW inputs, the CCDC output requires additional image processing to transform the input image to a final processed image. This processing can be performed either on-the-fly in the preview engine, or in software on the IVA2.2 subsystem. In parallel, RAW data input to the CCDC can be used for computing statistics (H3A, histogram) to eventually control image/video tuning parameters. The CCDC module supports the following features:

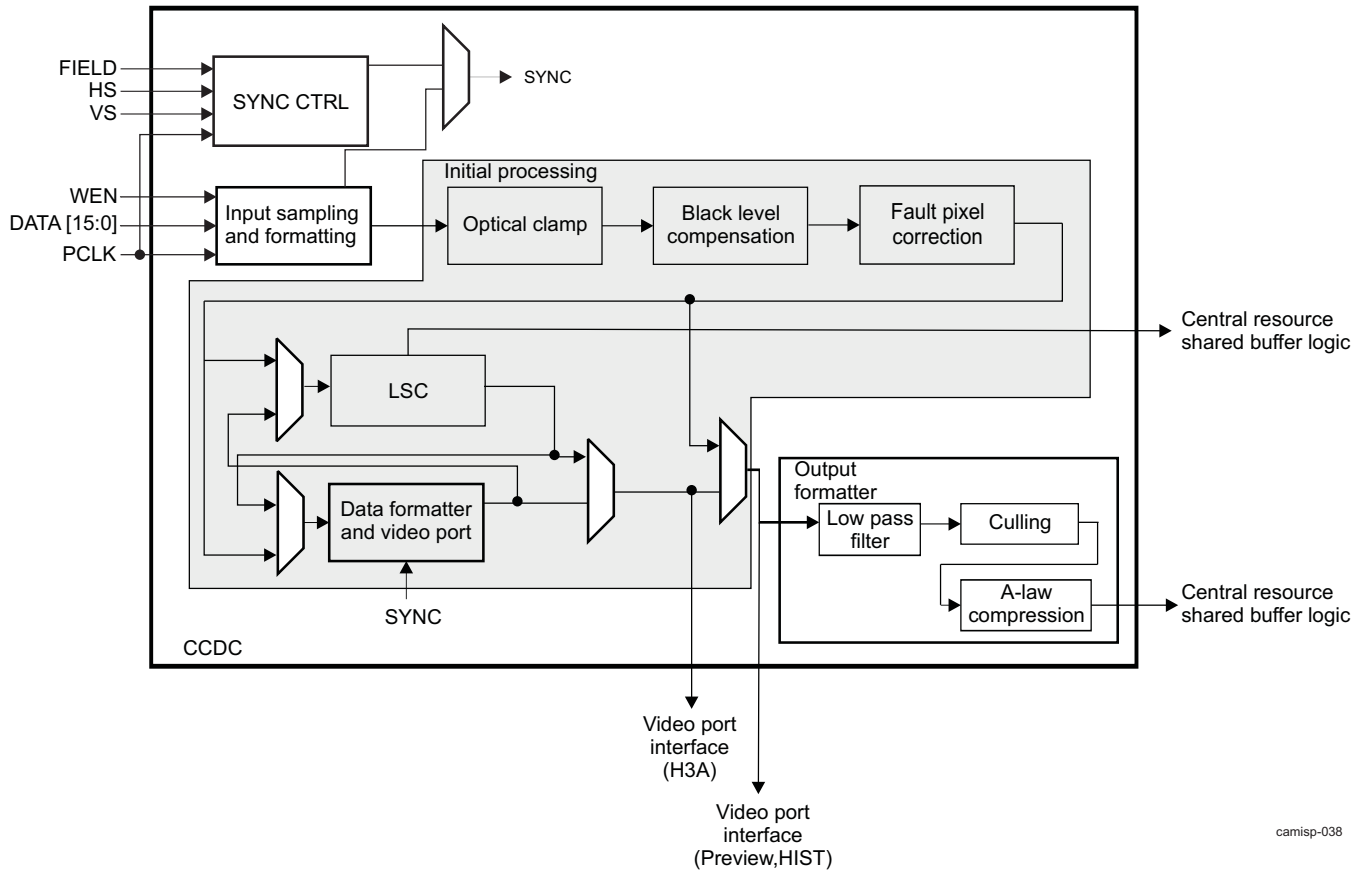

- **Image sensors:** Supports most image sensors (resolutions up to 4096 x 4096).

- **CCDC interface:** The camera ISP module interface comes either from the external parallel interface or from the output of the CSI receiver (through the video-port interface). It is a 16-bit interface. To raise this maximum 16-bit interface, the bridge data-lane shifter before the CCDC module allows the packing of 8-bit data into 16 bits (not supported with ITU mode):
  - Data up to 8-bit at 130 MHz can be transferred to memory.
  - Data up to 10-bit at 75 MHz can be processed by the image pipeline or transferred to memory.
  - Data up to 12-bit at 75 MHz can be transferred to memory or internally converted into 10-bit data to be processed by the image pipeline.
  - Supports two synchronization modes:
    - **SYNC mode:** In this mode, the cam\_hs and cam\_vs signals use dedicated wires. Synchronization signals are provided by either the sensor or the camera ISP. This mode works with 8-, 10-, 11-, and 12-bit data. It supports both progressive and interlaced image-sensor modules.
    - **ITU mode:** In this mode, the image-sensor module provides an ITU-R BT 656-compatible data stream. Horizontal and vertical synchronization signals are not provided to the interface. Instead, the data stream embeds SAV and EAV synchronization code. This mode works in 8- and 10-bit configurations.
- **RAW data processing:** Output data can go directly to memory for software processing, or to the PREVIEW module for further processing. The operations include:
  - Optical clamp
  - Black-level compensation
  - Faulty-pixel correction
  - 2D map based lens-shading compensation
  - Data formatter
  - Output formatter
- **YUV data processing:** The output data can go directly to memory for software processing or to the resizer module for further processing. The operations include:
  - DC subtract
  - Culling
  - Output formatter
- **Memory ports:** The CCDC module can access memory as a master through the CRSBL, so it does not require the assistance of the system DMA.

#### 12.4.6.1.2 CCDC Block Diagram

Figure 12-72 shows the top-level block diagram of the CCDC module.

Figure 12-72. CCDC Block Diagram

camisp-038

Table 12-28 summarizes allowed data flows through the CCDC.

Table 12-28. Allowed Data Flows Through the CCDC

Module		6/7 Bits RAW Format, SYNC Mode	8/10 Bits RAW Format, SYNC Mode	11/12 Bits RAW Format, SYNC Mode	8/10 Bits YUV4:2:2 Format, BT656 Mode	8/10 Bits YUV4:2:2 Format, SYNC Mode 75 MHz	8/10 Bits YUV4:2:2 Format, SYNC Mode 130 MHz	Other Formats (JPEG...), SYNC Mode
Bridge data-lane shifter	Bridge						+	
CCDC-SYNC CTRL	SYNC CTRL	+	+	+		+	+	+
CCDC-Input sampling and formatting	BT656 decoder				+			
CCDC-Initial processing	DC subtract	+	+	+	+	+	+	
	Optical black clamp	+	+	+				
	Black-level comp	+	+	+				
	Faulty-pixel correction	+	+	+				
CCDC-Data formatter	Data formatter	+	+					

**Table 12-28. Allowed Data Flows Through the CCDC (continued)**

Module		6/7 Bits RAW Format, SYNC Mode	8/10 Bits RAW Format, SYNC Mode	11/12 Bits RAW Format, SYNC Mode	8/10 Bits YUV4:2:2 Format, BT656 Mode	8/10 Bits YUV4:2:2 Format, SYNC Mode 75 MHz	8/10 Bits YUV4:2:2 Format, SYNC Mode 130 MHz	Other Formats (JPEG...), SYNC Mode
	Shading compensator		+					
	Preview, H3A, HIST data path	+	+					
CCDC-Output formatter	Pixel selection	+	+	+	+	+	+	
	Low-pass filter	+	+	+				
	Culling	+	+	+	+	+	+	
	A-Law	+	+	+				
	Resizer data path				+	+	+	
	Memory data path	+	+	+	+	+	+	+

**NOTE:** Data from CS1a or CS1b receivers corresponds to SYNC columns.

The data flow through the module differs, depending on whether the input is RAW data or YUV data. It also depends on the application scenario.

For RAW8/10 data ([CCDC\\_SYN\\_MODE](#) [13:12] INPMODE = 0 [CCDC\\_REC656IF](#) [0] REC656ON = 0), the following functions apply:

- Video-preview and video-capture data flows can pass through the optical-clamp, black-level compensation, faulty-pixel correction, lens-shading compensator, and data-reformatter submodules. Output is transmitted to the HISTH3A modules for further processing.
- JPEG still-image-capture data flow passes through the optical clamp, black-level compensation, faulty-pixel correction, lens-shading compensator, and data-reformatter submodules. Then the data flow is sent to memory through the SBL, Circular buffer, and MMU to be read by the external JPEG CODEC.
- RAW still-image-capture data flow typically passes through the optical clamp, black-level compensation, faulty-pixel correction, lens-shading compensator and output-formatter submodules.

For YUV data ([CCDC\\_SYN\\_MODE](#) [13:12] INPMODE = 1 or 2 [CCDC\\_REC656IF](#) [0] REC656ON = 1), the following functions apply:

- Data can be written to memory directly through the central-resource SBL module or sent to the resizer module for upscaling or downscaling.

For JPEG data coming from the camera parallel interface (CPI), the following settings apply for proper CCDC configuration:

- [ISP\\_CTRL](#)[29] [CCDC\\_WEN\\_POL](#) = Depending on the JPEG sensor
- [CCDC\\_SYN\\_MODE](#)[5] [EXWEN](#) = 1
- [CCDC\\_SYN\\_MODE](#)[13:12] [INPMOD](#) = 0
- [CCDC\\_SYN\\_MODE](#)[11] [PACK8](#) = 1
- [CCDC\\_SYN\\_MODE](#)[10:8] [DATSIZ](#) = 7
- [CCDC\\_CFG](#)[8] [WENLOG](#) = 1
- [CCDC\\_VERT\\_LINES](#)[14:0] [NLV](#) = 0
- [CCDC\\_HSIZE\\_OFF](#)[15:0] [LNOFST](#) = 0

### 12.4.6.1.3 CCDC Functional Operations

#### 12.4.6.1.3.1 SYNC CTRL Module

The SYNC CTRL module receives the pixel-clock signal from the image sensor (PCLK). The module can be slave or master of the horizontal and vertical synchronization signals (HS and VS) and of the field-identification signal (FIELD).

The HS, VS, and FLD signals can be set as inputs or outputs. The polarity of the HS, VS, and FLD signals can be set as positive or negative. If the HS, VS, and FLD signals are output, the signal length can be set.

#### 12.4.6.1.3.2 Input Sampling and Formatting

- Data is latched by the pixel clock.
- Pixel-clock polarity can be either rising- or falling-edge. This is set through [ISP\\_CTRL](#) [4] PAR\_CLK\_POL.
- Data can be interpreted as normal or inverted ([CCDC\\_SYN\\_MODE](#)[6] DATAPOL).
- For RAW data:
  - Data is clipped to the number of LSBs specified in the [CCDC\\_SYN\\_MODE](#) [10:8] DATSIZ field. This also sets the maximum data size allowed in subsequent clipping/limiting operations and is the output data alignment if data is written to memory.
- For YUV data (BT656 or SYNC mode):
  - The MSB of the chroma signal can also be inverted ([CCDC\\_CFG](#) [13] MSBINVI). It adds 128 to chrominance signals, to be compatible with several sensors.
- BT656 decoder: Separates data and synchronization signals. This module outputs HS, VS, and FIELD signals.

#### 12.4.6.1.3.3 CCDC Initial Processing

##### Optical Clamp

The optical black clamping function provides a means of averaging the optically black pixels and subtracting that value from each input pixel as a first step. The goal is to remove an offset caused by the sensor technology.

The averaging circuit takes an average of masked (black) pixel values from the image sensor, averaging pixels at the start ([CCDC\\_CLAMP](#) [24:10] OBST) of each line ([CCDC\\_CLAMP](#) [30:28] OBSLEN) and for the number of indicated lines ([CCDC\\_CLAMP](#) [27:25] OBSLN), plus an optional gain adjustment ([CCDC\\_CLAMP](#) [4:0] OBGAIN), and subtracting this value from the image data at the succeeding line. Users can control the position of the black pixels, the number of pixels (1, 2, 4, 8, or 16) in each line averaged, and the averaged number of lines (1, 2, 4, 8, or 16).

Alternately, users can disable black clamp averaging ([CCDC\\_CLAMP](#) [31] CLAMPEN) and select a constant black value for subtraction ([CCDC\\_DCSUB](#) [13:0] DCSUB), instead of using the calculated average value.

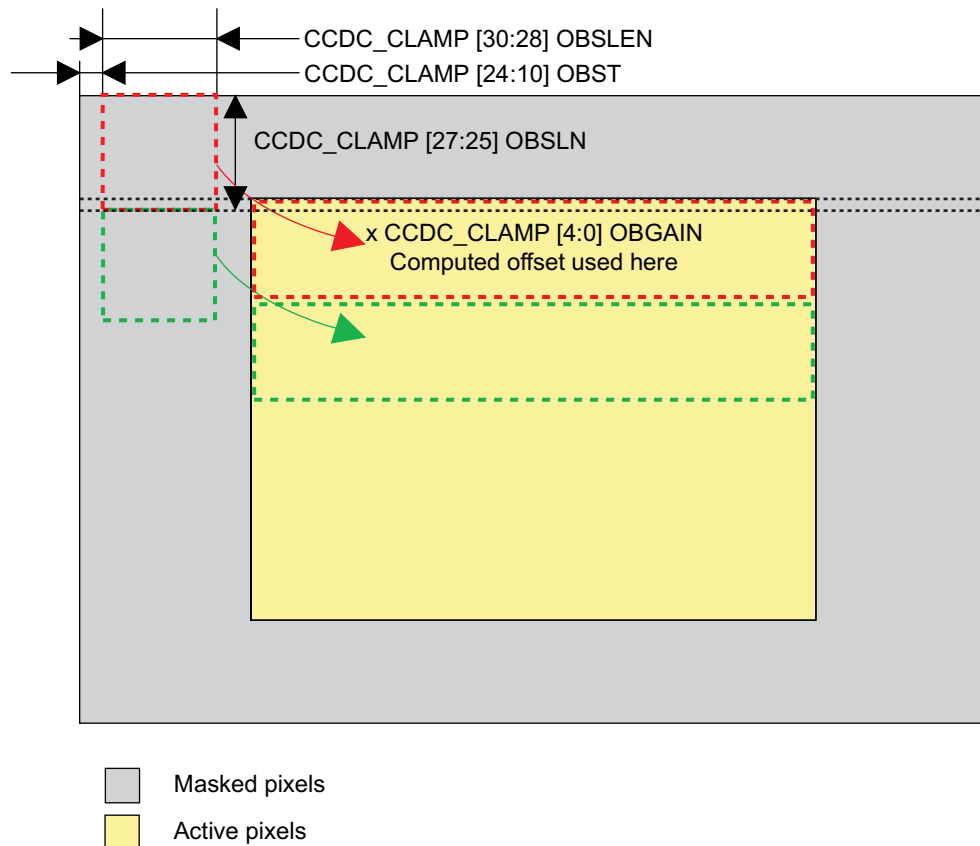

---

**NOTE:** For YUV data, this operation subtracts a fixed value ([CCDC\\_DCSUB](#) [13:0] DCSUB) from the luminance sample. To disable this operation, set the subtraction value to zero.

This function does not clip negative results to 0 for YUV 8 bit input or REC656 input modes ([CCDC\\_SYN\\_MODE](#) [13:12] INPMOD == 2 || [CCDC\\_REC656IF](#) [0] REC656ON == 1).

---

Figure 12-73 shows an optical clamp representation.

**Figure 12-73. Optical Clamp Representation**

camisp-106

### Black-Level Compensation

After the optical clamp, black-level compensation is applied to the data. In this operation, a fixed value, depending on the color (R/Ye, Gr/Cy, Gb/G, and B/Mg), can be subtracted from the data. The offset ([CCDC\\_BLKCOMP](#) register, fields R\_YE, GR\_CY, GB\_G, B\_MG) applied to each data sample is selected according to the pixel position (0/1/2/3) and the color (0/1/2/3) specified for each pixel position ([CCDC\\_COLPTN](#)). The color pattern definition is flexible to accommodate different sensor types (such as Bayer CFA sampling, VGA Movie Mode).

### Faulty-Pixel Correction

Faulty-pixel correction in the CCD module requires the camera driver to have information about the image-sensor faulty-pixel number and positions. This method leads to the best image quality. However, if the position of the faulty pixels is unavailable to the camera driver, it can apply another faulty-pixel correction algorithm in the preview module. This algorithm leads to lower-quality images.

The CCD module implements an optional ([CCDC\\_FPC](#) [15] FPCEN) faulty-pixel correction operation using a look-up table stored in external memory, which contains information about the horizontal and vertical positions of the pixels to be corrected, as well as the type of operation to be performed on the pixels. The [CCDC\\_FPC\\_ADDR](#) register specifies the starting address in memory for the faulty-pixel correction table.

---

**NOTE:** The memory address must be 64-byte-aligned (6 LSB are ignored).

---

---

**NOTE:** For YUV data, the faulty-pixel correction operation is not applicable and must be disabled/bypassed ([CCDC\\_FPC](#) [15] FPCEN).

---

#### 12.4.6.1.3.4 Data Formatter, Lens-Shading Compensation, and Video-Port Interface

---

**NOTE:** For YUV data, the data formatter, lens-shading compensation, and video-port interface must be bypassed ([CCDC\\_FMTCFG](#) [15] VPEN = 0x0 and [CCDC\\_SYN\\_MODE](#) [18] VP2SDR = 0x0).

---

The data-formatter module can be enabled to rearrange data after the faulty-pixel correction operation. It is intended to be used:

- When output data lines from the CCDIC include pixels from multiple resolution lines. Internally, these sensors combine pixels from multiple horizontal lines into one output pseudoline.
- To smooth bandwidth. This helps reduce peak bandwidth when image cropping is used with the resizer.

The reformatter module performs the decomposition before the remainder of the normal CCDIC processing stages.

The lens-shading compensation (LSC) module can be placed at two different locations:

- Before the data reformatter. It can only be used for Bayer sensors. The H3A video port gets the shading corrected image.
- After the data reformatter. This setup is required for non-Bayer sensors. Histogram and preview modules get the shading corrected image; however, H3A receives a non-corrected image.

Video-port/data-formatter output can also be saved to memory (instead of the RAW data). When [CCDC\\_SYN\\_MODE](#) [18] VP2SDR is set to 1, video-port data is sent to the output formatter. In addition, the [CCDC\\_SYN\\_MODE](#) [17] WEN bit must be enabled to store the output to memory.

The data-formatter and video-port interfaces are only 10 bits wide; therefore, the input data must be adjusted as it enters these modules. For flexibility, the bits to be retained can be selected by [CCDC\\_FMTCFG](#) [14:12] VPIN.

The reformatter decomposes each input line into multiple output lines with new, internally generated HS/VS signals. The reformatter sends it to memory or to other camera ISP modules. These new HS/VS signals, rather than the original sensor HS/VS signals, then gate the downstream processing.

##### Conversion Area Select Parameters

When the data formatter is enabled, HS/VS signals are still generated as output ([CCDC\\_SYN\\_MODE](#) [16] VDHDEN = 0x1). The settings for these output signals are in the following fields:

- [CCDC\\_HD\\_VD\\_WID](#)[27:16] HDW
- [CCDC\\_HD\\_VD\\_WID](#)[11:0] VDW
- [CCDC\\_PIX\\_LINES](#)[31:16] PPLN
- [CCDC\\_PIX\\_LINES](#)[15:0] HLPRF

---

**NOTE:** These four registers are not used when HS/VS signals are input signals ([CCDC\\_SYN\\_MODE](#) [16] VDHDEN = 0x0).

---

---

**NOTE:** The settings reflect those for the sensor readout frame, not the resultant reformatted frame.

---

Registers [CCDC\\_FMT\\_HORZ](#) and [CCDC\\_FMT\\_VERT](#) control the interpretation of the input data frame when the data formatter is enabled.

Registers [CCDC\\_HORZ\\_INFO](#), [CCDC\\_VERT\\_START](#), and [CCDC\\_VERT\\_LINES](#) control the interpretation of the input data frame in normal mode (when the data formatter is not enabled).

[Figure 12-74](#) shows the data formatter conversion area selection.

**Figure 12-74. Data Formatter Conversion Area Selection**

camisp-045

### Line Decomposition

When enabled, the reformatter can be configured to operate in line-alternating mode or program mode (CCDC\_FMTCFG [1] LNALT).

When line-alternating mode is enabled, the reformatter swaps even and odd lines. Basically, the 0<sup>th</sup> input line is output as the first line, the first input line is output as the 0<sup>th</sup> line, and so on. If this option is set, the start and number of lines for the formatter (CCDC\_VERT\_START and CCDC\_VERT\_LINES) must be even.

In program mode, or normal reformatter mode, the goal is to convert a single line of movie mode data to 1, 2, 3, or 4 lines of Bayer data. Each incoming line is decomposed according to the data-formatter settings and buffered into an internal line memory. The readout of the resultant multiple reformatted lines occurs as the next input line is being read from the sensor (and reformatted) to ensure that all output lines are fully constructed. The reformatter is subject to the restrictions listed in Table 12-29.

**Table 12-29. Reformatter Output Limitations**

Number of Output Lines/Input Line	Max Pixels/Output Line
1	4 * 1376
2	2 * 1376
3	1 * 1376
4	1 * 1376

The reformatter derives its flexibility from supporting up to 8 different addresses and a program that can contain up to 16 entries each for the odd and even lines. Each of the 8 addresses supports either autoincrement or autodecrement. This capability is the key for supporting a multitude of readout patterns. The following examples show the programmability of the reformatter. Decomposition is controlled by defining the following parameters:

- **CCDC\_FMTCFG [3:2] LNUM**  
Number of lines into which each input line is to be decomposed
- **CCDC\_FMTCFG [11:8] PLEN\_EVEN**  
Number of program entries on even line
- **CCDC\_FMTCFG [7:4] PLEN\_ODD**  
Number of program entries on odd line
- **CCDC\_FMT\_ADDR<sub>i</sub> (i=0:7)**  
Output line in which the original pixel is to be placed, and initial address on the output line
- **CCDC\_PRGEVEN0** or **CCDC\_PRGEVEN1**  
Program to be run on the even input lines
- **CCDC\_PRGODD0** or **CCDC\_PRGODD1**  
Program to be run on the odd input lines

The `CCDC_FMT_ADDR_i` registers define 8 address pointers (ADDR0 to ADDR7) that define which output line the input pixel belongs to, and the starting address (position) on that output line. Users can use up to 8 address pointers. The address pointer can be incremented or decremented, depending on the input pixel pattern. The address value computed should always follow the reformatter rules as formerly stated and should never be negative.

### **Lens-Shading Compensation**

- *Overview*

The purpose of the LSC function is lens-shading correction by multiplying an image with a gain factor 2-D map, pixel by pixel. The image must be in Bayer CFA format having a 2x2 color pattern. The gain factor map is stored in external memory downsampled, and is accessed and upsampled by the LSC module before being applied to the pixel data.

The LSC function is useful for lens-shading compensation and for scene- and image-dependent lighting adjustment. Downsampled gain map reduces memory requirements for storage and bandwidth requirements for access of the gain maps in external memory.

- *Features supported*

- The memory stored gain map is MxN downsampled, M being the horizontal sampling factor, N being the vertical sampling factor, M and N being {4, 8, 16, 32, 64} independently and N M
- 8-bit entries in the gain map (in U8Q8, U8Q7, U8Q6, and U8Q5 format with optional base of 1.0)
- Up to 10-bit unsigned image data input/output
- Up to 4096 x 3072 image dimension

- *Functional description*

The lens-shading correction module multiplies an image by a gain map that is stored downsampled in memory. The gain map can be dependent on aperture, lens-shading characteristics, and other photographic settings. It is generally used to correct the dim corner effect, but can also be used to implement adaptive lighting adjustment.

Separate horizontal and vertical sampling factors allow the lens-shading correction to work with the normal 1:1 aspect ratio image pixels, as well as tall-and-skinny pixels typical in the sensors preview mode image data.

### 12.4.6.1.3.5 Output Formatter

The output formatter starts with a framing selection to limit the processing area by setting [CCDC\\_HORZ\\_INFO](#), [CCDC\\_VERT\\_START](#), and [CCDC\\_VERT\\_LINES](#) registers. This framing selection is applied in addition to the framing applied at the beginning and at the end of the data formatter operation if the video-port path to memory is selected ([CCDC\\_SYN\\_MODE](#) [18] VP2SDR).

The option to send the CCDC output to the resizer module ([CCDC\\_SYN\\_MODE](#) [19] SDR2RSZ) should not be used when in RAW data mode, because the resizer operates only on YUV format data. Use the preview module when resizing is desired in RAW data mode.

#### Low-Pass Filter (LPF)

An optional horizontal low-pass antialiasing filter can be applied ([CCDC\\_SYN\\_MODE](#) [14] LPF) after reframing. The low-pass filter consists of a simple 3-tap (1/4, 1/2, and 1/4) filter. Two pixels on the left and two pixels on the right of each line are cropped if the filter is enabled. Use of the LPF is intended for bandwidth reduction if culling is enabled.

---

**NOTE:** For YUV data, the LPF must be disabled ([CCDC\\_SYN\\_MODE](#) [14] LPF = 0x0).

---

#### Culling

An optional culling operation can be enabled ([CCDC\\_CULLING](#) register). This operation allows selected pixel data to be culled (deleted) from a line ([CCDC\\_CULLING](#) [31:24] CULHEVN, [CCDC\\_CULLING](#) [23:16] CULHODD - 8-bit repeating mask, one per field) and selected lines to be culled from a frame ([CCDC\\_CULLING](#) [7:0] CULV).

[Figure 12-75](#) is an example of how register values apply the decimation pattern to the data. The red pixels are saved to memory and the white pixels are discarded. In this example, [CCDC\\_CULLING](#) = 0x239A0066:

- [CCDC\\_CULLING](#) [31:24] CULHEVN = 0x23
- [CCDC\\_CULLING](#) [23:16] CULHODD = 0x9A
- [CCDC\\_CULLING](#) [7:0] CULV = 0x66

---

**NOTE:** Culling can be used with YUV data, but care must be taken to preserve the YUV422 output format.

---

**Figure 12-75. CCDC/Culling: Example for Decimation Pattern**

**A-Law Compression**

An optional 10-to-8-bit A-Law compression using a fixed A-Law table can be applied (CCDC\_ALAW [3] CCDTBL) as the final processing stage. Using this causes data width to be reduced to 8 bits and allows packing to 8 bits/pixel when saving to memory. Because data resolution can be greater than 10 bits at this stage, the 10 bits for input to the A-Law operation must be selected (CCDC\_ALAW [2:0] GWDI).

The preview module has an inverse A-Law table (A-Law decompression) option so that this nonlinear operation can be reversed if this saved data is to be read back in for further processing.

---

**NOTE:** A-Law compression should not be used (CCDC\_ALAW [3] CCDTBL = 0) with YUV data.

---

Figure 12-76 show the A-Law table.

**Figure 12-76. A-Law Table**

## Line-Output Control

---

**NOTE:** Line-output control can be used with YUV data.

---

The CCDC final stage is line-output control, which controls how the input sensor lines are written to memory. The value of [CCDC\\_SDR\\_ADDR](#) [31:0] ADDR defines the starting address where the frame should be written in memory. The value of [CCDC\\_HSIZE\\_OFF](#) [15:0] LNOFST defines the distance between two lines for each output line to memory. The starting address and line-offset values should be aligned to 32-byte boundaries; that is, either 16 or 32 pixels, depending on the [CCDC\\_SYN\\_MODE](#) [11] PACK8 setting. Register [CCDC\\_SDOFST](#) can be used to define additional offsets, depending on the field ID and even/odd line numbers. This provides a means to deinterlace an interlaced 2-field input and to invert an input image vertically. See [Table 12-30](#).

**Table 12-30. CCDC\_SDOFST Description**

Register	Description
<a href="#">CCDC_SDOFST</a> [14] FIINV	Invert interpretation of the field ID signal
<a href="#">CCDC_SDOFST</a> [13:12] FOFST	Offset, in lines, of field = 1
<a href="#">CCDC_SDOFST</a> [11:9] LOFTS0	Offset, in lines, between even lines on even fields (field 0)
<a href="#">CCDC_SDOFST</a> [8:6] LOFTS1	Offset, in lines, between odd lines on even fields (field 0)
<a href="#">CCDC_SDOFST</a> [5:3] LOFTS2	Offset, in lines, between even lines on odd fields (field 1)
<a href="#">CCDC_SDOFST</a> [2:0] LOFTS3	Offset, in lines, between odd lines on odd fields (field 1)

### Line Output Control: 2D Addressing Example

The CCDC memory port can be configured to write a subimage into a bigger image buffer. This feature is useful for overlaying a video preview flow with the rest of the display. To use this feature, the [CCDC\\_SDR\\_ADDR](#) [31:0] ADDR register points to the first pixel to write and the [CCDC\\_SDOFST](#) [13:12] FOFST is set to the size of one line of the destination buffer.

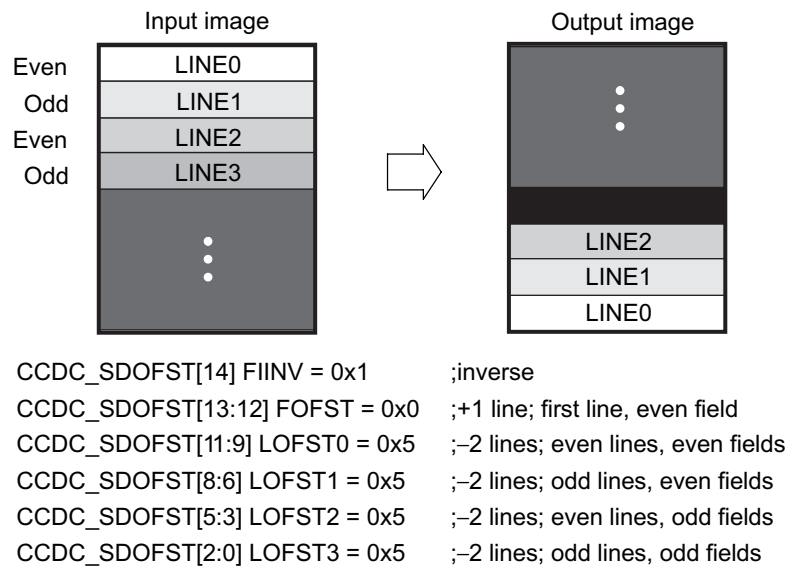

---

**NOTE:**

- This mode can be used only when the source and destination buffers use the same image format.
  - 2D addressing is also supported by other camera ISP modules.
- 

### Line-Output Control: Examples

[Figure 12-77](#) shows an example of sample formats of input and output images.

**Figure 12-77. CCDC/Line-Output Control: Sample Formats of Input and Output Images**

camisp-051

### Output Format

The data bits comprising each pixel are stored in the lower bits of a 16-bit memory word and the unused bits are zero-filled. The memory data format is shown in [Table 12-31](#). The format is determined by the [CCDC\\_SYN\\_MODE](#) [10:8] DATSIZ field.

If 8-bit data is input, or if A-Law compression is applied, the data can be packed through the [CCDC\\_SYN\\_MODE](#) [11] PACK8 setting so that a pixel occupies only 8 bits.

Data is output to memory only when enabled through the [CCDC\\_SYN\\_MODE](#) [17] WEN setting. The pixels are ordered in little-endian format.

**Table 12-31. Memory Output Format for RAW Data**

	Upper word		Lower word	
	MSB(31)	LSB(16)	MSB(15)	LSB(0)
16 bit	Pixel 1		Pixel 0	
15 bit	0	Pixel 1	0	Pixel 0
14 bit	0	Pixel 1	0	Pixel 0
13 bit	0	Pixel 1	0	Pixel 0
12 bit	0	Pixel 1	0	Pixel 0
11 bit	0	Pixel 1	0	Pixel 0
10 bit	0	Pixel 1	0	Pixel 0
9 bit	0	Pixel 1	0	Pixel 0
8 bit	0	Pixel 1	0	Pixel 0
8-bit packed	Pixel 3	Pixel 2	Pixel 1	Pixel 0

**NOTE:** YUV data is stored in memory in packed YUV422 mode, using two pixels per 32 bits, as shown in [Table 12-32](#).

**Table 12-32. Memory Output Format for YUV Data**

Memory Address	Upper Word		Lower Word	
	MSB(31)	LSB(16)	MSB(15)	LSB(0)
N	Y1	Cr0	Y0	Cb0
N + 1	Y3	Cr1	Y2	Cb1
N + 2	Y5	Cr2	Y4	Cb2

#### 12.4.6.1.4 DMA

The CCDC module is a master. It has its own address generator and sends addresses and data to the central-resource shared-buffer logic. The central-resource shared-buffer logic arbitrates the data requests and generates the bursts to memory.

#### 12.4.6.1.5 Memories

The CCDC module has one memory:

- REFORMATTER BUFFER: 3 1376 40 bits
- LSC PREFETCH BUFFER: 1536 32 bits

### 12.4.7 Video-Processing Back End

The video-processing back end (VPBE) comprises the preview and resizer modules.

#### 12.4.7.1 Preview Engine Features

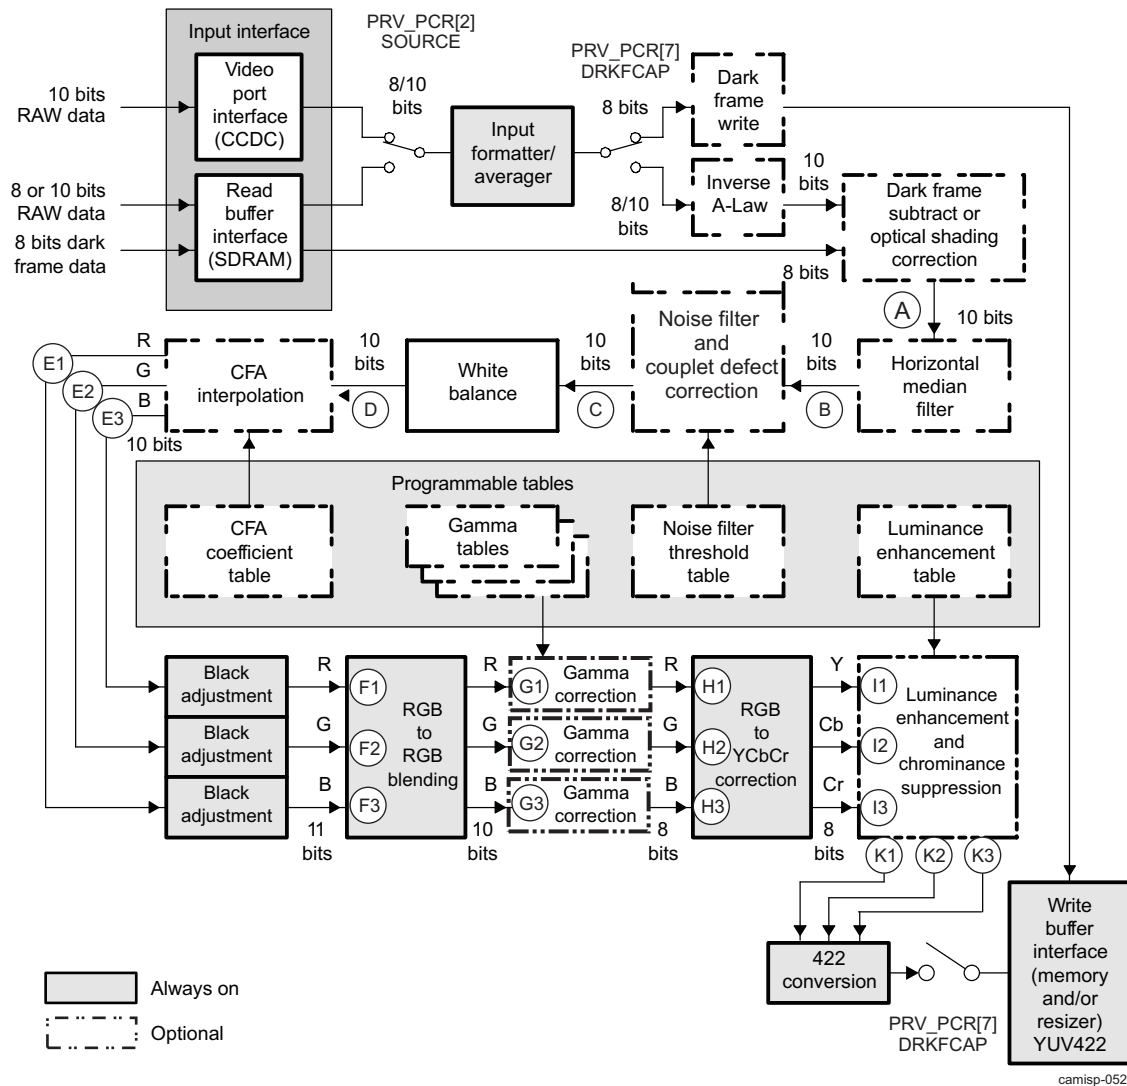

The preview module is responsible for transforming data from a RAW image sensor into YUV422 data that is amenable to still-image encoding, video encoding, or display. It supports the following features:

- Flexible input: Module input data can come from the RAW image sensor (10 bits) or from memory (8 or 10 bits).
- Flexible input formats: Bayer RGB color filter array, complementary-color filter array, Super CCD Honeycom™ sensors
- Horizontal averaging by a factor of 2, 4, or 8 in the horizontal direction. The preview module can output a maximum of only 3312 pixels horizontally due to fixed memory-line sizes.
- A-Law decompression: Transforms nonlinear 8-bit data to 10-bit linear data. The CCDC module can perform A-Law compression.
- Noise reduction and faulty-pixel correction:
  - Dark-frame capture and subtraction
  - Horizontal median filter
  - Programmable noise filter: 33 kernel of same color pixels
  - Couplet faulty-pixel correction
- Digital gain and white balance
- Programmable CFA interpolation that operates on a 55 grid
- Programmable RGB-to-RGB blending matrix: 9 coefficients for the 33 matrix
- Programmable gamma correction: 1024 entries for each color held in local memory
- Programmable RGB-to-YUV color conversion: 9 coefficients for the 33 matrix
- Luminance enhancement (nonlinear), chrominance suppression and offset

##### 12.4.7.1.1 Preview Block Diagram

[Figure 12-78](#) shows the preview engine block diagram.

Figure 12-78. Preview Engine Block Diagram

### 12.4.7.1.2 Input Interface

The preview engine receives RAW image/video data from the video port interface through the CCDC or from the read buffer interface through the memory ([PRV\\_PCR \[2\] SOURCE](#)). When the source of input data is the CCDC, the input data is always 10 bits wide. When the source of input data is memory (read buffer interface), the data can be 8 or 10 bits wide. Use the [PRV\\_PCR\[4\] WIDTH](#) field to set the input data width. The 8 bits can be linear or nonlinear (A-Law compressed).

In addition, the preview engine can fetch a dark frame from memory, with each pixel 8 bits wide.

The frame-input size is configured using the [PRV\\_HORZ\\_INFO](#) and [PRV\\_VERT\\_INFO](#) registers.

If the input source is the CCDC, the input height set in the preview engine must be less than or equal to the output height of the video-port output of the CCDC. The input width must be at least 4 pixels smaller than the CCDC output width (SPH = 2; EPH = 2 pixels before the last pixel sent from the CCDC).

The input memory address ([PRV\\_RSDR\\_ADDR](#)) and line offset ([PRV\\_RADR\\_OFFSET](#)) registers should be aligned on 32-byte boundaries when the input source is set to memory. The dark-frame input address ([PRV\\_DSDR\\_ADDR](#)) and line offset ([PRV\\_DRKF\\_OFFSET](#)) should also be aligned on 32-byte boundaries when the dark-frame subtract function is enabled.

When the input source is memory, the preview engine always operates in one-shot mode. After enabling the preview engine and processing a frame, the enable bit is turned off and it is up to firmware to reenable it to process the next frame from memory.

When the input source is the CCDC, the preview engine can be configured to operate in one-shot mode or continuous mode ([PRV\\_PCR \[3\]](#) ONESHOT).

The SBL image data read port is shared between the preview and CSI1 receiver module. When the image is read from memory, the read port must be affected to the preview receiver module by writing 0 into the [ISP\\_CTRL\[27\]](#) SBL\_SHARED\_RPORTA. Programmers must ensure that the CSI1 module does not use this port before switching to the preview module.

### 12.4.7.1.3 Input Formatter/Averager

Preview-engine output is limited to 3312 pixels per horizontal line due to line memory-width restrictions in the noise filter and CFA interpolation blocks. To support sensors that output more than 3312 pixels per line, an averager is incorporated to downsample by factors of 1 (no averaging), 2, 4, or 8 in the horizontal direction ([PRV\\_AVE \[1:0\]](#) COUNT). The horizontal distance between two consecutive pixels of the same color to be averaged is selectable from among 1, 2, 3, or 4 for both even ([PRV\\_AVE \[3:2\]](#) EVENDIST) and odd ([PRV\\_AVE \[5:4\]](#) ODDDIST) lines. This must be configured to match the input pattern type.

For example, a Bayer pattern has a horizontal distance of two pixels of the same color for both even and odd lines.

Valid output of the input formatter/averager is either 8 or 10 bits wide.

[Figure 12-79](#) shows the horizontal distances for different patterns.

**Figure 12-79. Horizontal Distances for Different Patterns**

Bayer format with R/Gr and Gb/B in alternate lines  
Horizontal distance between same colors is 2

camisp-308

### 12.4.7.1.4 Dark-Frame Write

The preview engine is capable of capturing and saving a dark frame to memory instead of performing conventional processing steps ([PRV\\_PCR \[7\]](#) DRKFCAP).

This dark frame can later be subtracted from the RAW image data to eliminate the repeatable baseline noise level in the frame.

Each input pixel is written as an 8-bit value; if the input pixel value is greater than 255, it is saturated to 255. If a dark pixel is greater than 255, it is more likely to be faulty, and can be corrected by the faulty-pixel correction module in the CCDC. If properly corrected, the value must be less than 255 when it reaches the preview engine.

The [PRV\\_WSDR\\_ADDR](#) and [PRV\\_WADD\\_OFFSET](#) registers must be used to indicate the output address and line offset, respectively, of the dark-frame output in memory.

### 12.4.7.1.5 Inverse A-Law

To save memory capacity and bandwidth, the CCDC includes an option to apply 10-bit to 8-bit A-Law compression and to pack the sensor data to 1 byte per pixel. To process this data correctly, the inverse A-Law block is provided to decompress the 8-bit nonlinear data back to 10-bit linear data if enabled ([PRV\\_PCR \[5\]](#) INVALAW). Even if the inverse A-Law block is not enabled, but the input is still 8 bits ([PRV\\_PCR \[4\]](#) WIDTH), the data is-left shifted by 2 to make it 10-bit data. If the input is 10 bits wide, no operation is performed on the data.

---

**NOTE:** When A-Law compression in CCDC is enabled during dark-frame write, it must be enabled when the stored dark frame is used.

---

#### 12.4.7.1.6 Dark-Frame Subtract or Shading Compensation

The preview engine can fetch a dark frame containing 8-bit values from memory (8 bits in input are converted internally to 10 bits by adding two zeros to the left) and subtracting it, pixel by pixel, from the incoming input frame ([PRV\\_PCR \[6\] DRKFEN](#)). This function removes pattern noise in the sensor. The output of the dark-frame subtract operation is 10 bits wide (U10Q0).

There must be adequate memory bandwidth if this feature is enabled. If the data fetched from memory arrives late, the [PRV\\_PCR \[31\] DRK\\_FAIL](#) status bit is set to indicate a fail.

Instead of performing the dark-frame subtract, the preview engine can perform lens-shading compensation (if [PRV\\_PCR \[21\] SCOMP\\_EN](#) is set along with [PRV\\_PCR \[6\] DRKFEN](#)). In this case, the 8-bit unsigned value fetched from memory is multiplied by the incoming pixel, and the result is right-shifted by the number of bits specified by the [PRV\\_PCR \[24:22\] SCOMP\\_SFT](#) parameter (0-7 bits).

The SBL data read port is shared between the CCDC and preview module. The read port must be affected to the preview module by writing 0 into the [ISP\\_CTRL \[28\] SBL\\_SHARED\\_RPORTB](#). Programmers must ensure that the CCDC module does not use this port before switching to the preview module.

#### 12.4.7.1.7 Horizontal Median Filter

The preview engine contains a horizontal median filter that can help reduce temperature-induced noise effects. The input and output of the horizontal median filter are 10 bits wide (U10Q0).

---

**NOTE:** Line-width reduction: If the horizontal median filter is enabled, the preview engine reduces the length of the output line of this stage by 4 pixels (2 starting pixels -left edge and 2 ending pixels -right edge). For example, if the input size is 656x490 pixels, the output is 652x490 pixels. There is no truncation of input data line if this block is disabled.

---

#### 12.4.7.1.8 Noise Filter and Faulty Pixel Correction

The noise filter and couplet defect correction (CDC) operate on the same 3x3 matrix of same color pixels. Both functions can be enabled separately using the [PRV\\_PCR \[27\] DCOREN](#) and [PRV\\_PCR \[9\] NFEN](#) bits.

The faulty pixel correction function replaces the central pixel (x0) with one of the neighbors (x1-x8) in the following cases:

- When it has been identified as faulty.
- When the feature is enabled.

The noise filter modifies the central pixel when it is enabled.

---

**NOTE:** Some details of these features are not available in public domain

---

#### 12.4.7.1.9 White Balance

The white-balance module has a digital gain adjuster and a white-balance adjuster. In the digital gain adjuster ([PRV\\_WB\\_DGAIN \[9:0\] DGAIN](#)), RAW data is multiplied by a fixed-value gain, regardless of the color of the pixel to be processed.

In the white-balance gain adjuster ([PRV\\_WBGAIN](#)), RAW data is multiplied by a selected gain corresponding to the color of the processed pixel.

---

**NOTE:** Some details of this feature are not available in public domain

---

### 12.4.7.1.10 CFA Interpolation

The CFA function is responsible for providing full RGB data for each pixel. Depending on sensor type and configuration, interpolation and/or rephasing are required.

The CFA function can be enabled ([PRV\\_PCR](#) [10] CFAEN) and configured to different interpolation modes ([PRV\\_PCR](#) [14:11] CFAFMT).

---

**NOTE:** Some details of this feature are not available in the public domain.

---

#### 12.4.7.1.10.1 CFA for Bayer Modes

In Bayer modes, the CFA interpolation block is responsible for populating the missing color pixels at a given location, resulting in a 3-color RGB pixel. It does this by interpolating data from neighboring pixels of the same color.

---

**NOTE:** Some details of this feature are not available in the public domain.

---

#### 12.4.7.1.10.2 CFA Options

If the CFA interpolation block is disabled, the same input pixel is broadcast to all three output pixels.

---

**NOTE:** Image-size reduction: If CFA interpolation is enabled, the preview engine reduces the output of this stage. Two pixels/line in the left, right, top, and bottom edges are truncated in the Bayer/conventional and other modes.

---

If the CFA format is 2 downsampling in both horizontal and vertical directions, only 2 lines at the top and bottom of the image are truncated. The two left- and right-most pixels are processed.

#### 12.4.7.1.11 Black Adjustment

The CFA interpolation output is three pixels (red, blue, and green values) and this is fed as input to the black-adjustment module, which performs the following calculation for an adjustment of each color level:

$$data\_out = data\_in + bl\_offset$$

The `bl_offset` values for each color are programmable in the [PRV\\_BLKADJOFF](#) register and coded in S8Q0 format (-128..+127). A simple one addition and clip operation are processed in this module. The output `data_out` [10..0] is signed.

---

**NOTE:** Some details of this feature are not available in the public domain.

---

#### 12.4.7.1.12 RGB Blending

The RGB2RGB blending module has a general 33 square matrix and redefines the RGB data from the CFA interpolation module, which can be used as a function of a color correction. This is programmable ([PRV\\_RGB\\_MAT1](#), [PRV\\_RGB\\_MAT2](#), [PRV\\_RGB\\_MAT3](#), [PRV\\_RGB\\_MAT4](#), [PRV\\_RGB\\_MAT5](#), [PRV\\_RGB\\_OFF1](#), [PRV\\_RGB\\_OFF2](#)) so that the color spectrum of the sensor can be adjusted to the human color spectrum. The input is signed 11 bits and the output is unsigned 10 bits. The following calculation is performed in this module:

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \begin{bmatrix} MTX\_RR & MTX\_GR & MTX\_BR \\ MTX\_RG & MTX\_GG & MTX\_BG \\ MTX\_RB & MTX\_GB & MTX\_BB \end{bmatrix} \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix} + \begin{bmatrix} MTX\_OFFR \\ MTX\_OFFG \\ MTX\_OFFB \end{bmatrix}$$

camisp-E094

Gains are in S12Q8 format, and offsets are in S10Q0 format.

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix} + \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

camisp-E161

That leads to:

$$\begin{aligned} MTX\_RR &= MTX\_GG = MTX\_BB = 256 \\ others &= 0 \end{aligned}$$

camisp-E162

#### 12.4.7.1.13 Gamma Correction

Gamma correction is performed on each of the R, G, and B pixels separately by indexing programmable gamma look-up tables. Each table has 1024 8-bit entries. The input data value is used to index into the table and the table content is the output.

The gamma table can be bypassed ([PRV\\_PCR](#) [26] [GAMMA\\_BYPASS](#)). In this case, the output of the gamma correction is the 8 MSB of the 10-bit input. The gamma table can be written only while the preview engine is disabled.

#### 12.4.7.1.14 RGB to YCbCr Conversion, Luminance Enhancement, Chrominance Suppression, Contrast and Brightness, and 4:2:2 Downsampling and Output Clipping

##### 12.4.7.1.14.1 RGB-to-YCbCr Conversion

The RGB-to-YCbCr conversion module has a 33 square matrix and converts the RGB color space of the image data into the YCbCr color space. In this module, the following calculation is performed using the contents of the [PRV\\_CSC0](#), [PRV\\_CSC1](#), [PRV\\_CSC2](#), and [PRV\\_CSC\\_OFFSET](#) registers:

$$\begin{bmatrix} Y \\ Cb \\ Cr \end{bmatrix} = \begin{bmatrix} CSCRY & CSCGY & CSCBY \\ CSCRCB & CSCGCB & CSCBCB \\ CSCRCR & CSCGCR & CSCBCR \end{bmatrix} \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix} + \begin{bmatrix} YOFST \\ OFSTCB \\ OFSTCR \end{bmatrix}$$

camisp-E095

Gains are in S10Q8 format, and offsets are in S8Q0 format for chroma and U10Q0 for luma.

---

**NOTE:** Program the following values after reset for correct color conversion:

- [PRV\\_CSC2](#) [19:10] CSCGCR = 0x39E
  - [PRV\\_CSC2](#) [9:0] CSCRCR = 0x080
- 

##### 12.4.7.1.14.2 Nonlinear Luminance Enhancement

Nonlinear luminance enhancement functions as an edge enhancer (crossed in the horizontal direction). It can be enabled or disabled using the [PRV\\_PCR](#) [15] [YNENHEN](#) parameter. If it is enabled, a look-up table with 127 20-bit entries must be programmed. Each entry contains a 10-bit signed offset value in the MSBs, and a 10-bit signed slope in the LSBs.

---

**NOTE:** Some details of this feature are not available in the public domain.

---

### 12.4.7.1.14.2.1 Chrominance Suppression

Occasionally, in very bright portions of an image, only one or two of the color channels are saturated, while the remaining channel(s) are not. This can lead to a false-color effect. One common example is the appearance of pink where white should be. Chrominance suppression can be used to correct this issue.

Chrominance suppression can be enabled or disabled using the [PRV\\_PCR](#) [16] SUPEN parameter.

---

**NOTE:** Some details of this feature are not available in the public domain.

---

### 12.4.7.1.14.2.2 Contrast and Brightness

The luminance component can be adjusted for contrast (scaling/multiplication) and brightness (offset/addition). Contrast is set in the [PRV\\_CNT\\_BRT](#) [15:8] CNT field (U8Q4 precision), and brightness is set in the [PRV\\_CNT\\_BRT](#) [7:0] BRT field (U8Q0 precision).

### 12.4.7.1.14.2.3 Downsampling and Output Clipping

The 4:2:2 conversion module converts image data to YCbCr-4:2:2 format by averaging every other Cb and Cr component in the horizontal direction. Before outputting the data, the preview engine performs clipping on the YCC components separately. The minimum and maximum threshold values for the Y and C values are specified using the [PRV\\_SETUP\\_YC](#) register. If no clipping is required, the register must be set to its reset values of 0xFF for the maximum Y and C values, and 0 for the minimum Y and C values.

### 12.4.7.1.15 Write-Buffer Interface

The output of the preview engine may be passed directly to the resizer ([PRV\\_PCR](#) [19] RSZPORT) and/or written to memory ([PRV\\_PCR](#) [20] SDRPORT).

If the output is written to memory, the write address ([PRV\\_WSDR\\_ADDR](#)) and line offset ([PRV\\_WADD\\_OFFSET](#)) must be on 32-byte boundaries. The output format of the YCC data is programmable by setting the [PRV\\_PCR](#) [18:17] YCPOS parameter.

The final width and height of the output vary depending on which processing functions are enabled. [Table 12-33](#) indicates how many edge pixels/lines are truncated by enabling certain modules in the preview engine. These values must be subtracted from the input height and width after the averager to determine the size of preview-engine output.

**Table 12-33. Image Cropping by Preview Functions**

Image Cropping by Preview Functions		
Function	Pix/Line	Lines
Horizontal median filter	4	0
Noise filter	4	4
CFA (Bayer, Super CCD Honeycom or RGBE)	4	4
Color suppression OR luminance enhancement	2	0
Maximum total	14	8

---

**NOTE:** Different CFA modes are mutually exclusive.

---

## 12.4.7.2 Resizer

### 12.4.7.2.1 Features

The resizer module enables image upsampling and downsampling, see [Table 12-34](#). The following features are supported:

- Flexible input sources:
  - Preview module: Enables on-the-fly processing
  - Memory: Enables differed processing
- Flexible input format:
  - YUV422 packed data (16 bits)
  - Color-separate data (8 bits). The data must be contiguous in memory. The input source for the data must be the memory: not available for on-the-fly processing.
  - Same output format as input
- Upsampling: Up to 4. Enables digital zoom:
  - General polyphase filter:
    - Ratio of 1 to 4: 4 taps (horizontal and vertical) and 8 phases
- Downsampling: Down to 0.25:
  - General polyphase filter:
    - Ratio of 0.25 to 0.5: 7 taps (horizontal and vertical) and 4 phases
    - Ratio of 0.5 to 1: 4 taps (horizontal and vertical) and 8 phases
- Constraints:
  - The following input width (IW) and output width (OW) constraints must be obeyed due to limited on-chip memory resources.

**Table 12-34. Resizer Use Constraints**

Resizer Use Constraints			Horizontal Resizer Ratio	
			0.25 to 0.5	0.5 to 4
		7 taps	OW=1650	4 taps
Vertical resizer ratio	0.25 to 0.5	7 taps	OW=1650	OW=1650
	0.5 to 4	4 taps	OW=3312	OW=3312

- The horizontal resizer output rate must not exceed half the functional clock; that is, at 166-MHz functional clock, the horizontal resizer output rate must not exceed 83M pixels/s. This limitation applies only for the on-the-fly processing input source.
- Flexible resizing ratios: Independent resizing factors for the horizontal and vertical directions. The applicable ratio is 256/N, with N ranging from 64 to 1024.
- Programmable luminance enhancer
- Continuous and one-shot operation

#### 12.4.7.2.2 Block Diagram

The resizer module performs either upsampling (digital zoom) or downsampling on image/video data within a range of 0.25 to 4 resizing. The input source can be sent to either the preview engine/CCDC or memory, and the output is sent to memory.

The resizer module performs horizontal resizing, then vertical resizing, independently. Between them there is an optional edge-enhancement feature. This process is shown in [Figure 12-80](#).

**Figure 12-80. Resizer Process**

### 12.4.7.2.3 Input and Output Interfaces

The input source can be sent to either the preview engine/CCDC or memory ([RSZ\\_CNT \[28\] INPSRC](#)). The input width ([RSZ\\_IN\\_SIZE \[12:0\] HORZ](#)) must be at least 32 pixels.

#### 12.4.7.2.3.1 Preview Engine/CCDC Input Mode

In the preview engine/CCDC input mode, internal hardware synchronization signals define input frames. The horizontal starting byte ([RSZ\\_IN\\_START \[12:0\] HORZ\\_ST](#)) and vertical starting line ([RSZ\\_IN\\_START \[28:16\] VERT\\_ST](#)) define a starting pixel with respect to the upper-left corner of an input image (signaled through horizontal and vertical synchronization signals). The input width and height in the [RSZ\\_IN\\_SIZE](#) register specify the exact input range (relative to the starting pixel) necessary to generate an output frame of specified width/height.

---

**NOTE:** Care must be taken to ensure that the input sizes specified by the [RSZ\\_IN\\_START](#) and [RSZ\\_IN\\_SIZE](#) registers are less than or equal to the output from the preview engine or CCDC; otherwise, incorrect hardware operation may occur.

---

[RSZ\\_SDR\\_INADD](#) and [RSZ\\_SDR\\_INOFF](#) must be programmed to be 0x0 in this mode.

Also, the output ports of the CCDC ([CCDC\\_SYN\\_MODE \[19\] SDR2RSZ](#)) and preview engine ([PRV\\_PCR \[19\] RSZPORT](#)) to the resizer must be configured so that only one of them is enabled. If both are enabled, the CCDC gains control of this interface.

If input is from the CCDC, the output of the CCDC must be in YUV422 format (the resizer does not support resizing RAW data from the CCDC).

#### 12.4.7.2.3.2 Memory-Input Mode

In memory-input mode, the memory address in [RSZ\\_SDR\\_INADD](#) points to the 32-byte-aligned memory address where the starting pixel resides.

The horizontal starting pixel ([RSZ\\_IN\\_START \[12:0\] HORZ\\_ST](#)) defines a starting pixel within that 32-byte alignment; [HORZ\\_ST](#) is constrained to 0...15 for the 422 format, and 0...31 for the color-separated format.

The vertical starting pixel ([RSZ\\_IN\\_START \[28:16\] VERT\\_ST](#)) must be zero in memory-input mode. The [RSZ\\_SDR\\_INOFF](#) register specifies the address offset between rows of input data. The input width and height in the [RSZ\\_IN\\_SIZE](#) register specify the exact input range (relative to the starting pixel) necessary to generate an output frame of specified width/height.

[Figure 12-81](#) shows the resizer in memory-input mode.

Figure 12-81. Resizer in Memory-Input Mode

camisp-115

### 12.4.7.2.3.3 Output Interface

In both input modes, the **RSZ\_OUT\_SIZE** register specifies output width/height, the **RSZ\_SDR\_OUTADD** register specifies output starting pixel (upper-left corner) memory address, and the **RSZ\_SDR\_OUTOFF** register specifies memory address offset between the beginning of output rows. The resizer output always goes to memory.

**NOTE:** **RSZ\_SDR\_INADD**, **RSZ\_SDR\_OUTADD**, **RSZ\_SDR\_INOFF**, and **RSZ\_SDR\_OUTOFF** must be 32-byte-aligned; the lower 5 bits of the byte address are assumed to be zero.

Output-width constraints: The output width (**RSZ\_OUT\_SIZE** [11:0] HORZ) must be at least 16 pixels, and be even (so that the same number of Cb and Cr components is outputted). Due to the vertical memory size constraint, the output width (**RSZ\_OUT\_SIZE** [11:0] HORZ) cannot be greater than:

- 3312 pixels if the vertical resizing ratio is between 1/2 and 4 ((**RSZ\_CNT** [19:10] VRSZ + 1) = 512)
- 1650 pixels wide if the vertical resizing ratio is between 1/2 and 1/4 ((**RSZ\_CNT** [19:10] VRSZ + 1) = 512)

### 12.4.7.2.4 Horizontal and Vertical Resizing

In the rest of this section:

- HRSZ is used for **RSZ\_CNT** [9:0] HRSZ + 1.
- VRSZ is used for **RSZ\_CNT** [19:10] VRSZ + 1.

The resizer module can upsample or downsample image data with independent resizing factors in the horizontal and vertical directions. The HRSZ and VRSZ parameters can range from 64 to 1024 to give a resampling range from 4 to 0.25 (256/HRSZ or 256/VRSZ).

The resizer module uses the same resampling algorithm for the horizontal and vertical directions.

The resizing/resampling algorithm uses a programmable polyphase sample rate converter (resampler). The polyphase filter coefficients are programmable so that any user-specified filter can be implemented.

Figure 12-82 shows a general sample-rate converter where the resampling rate is equal to L/M.

**Figure 12-82. Typical Sample-Rate Converter**

L phases are used in a typical polyphase implementation. The resizer module, however, fixes the number of phases to 8 for a resizing range of 1/2 ~ 4 (RSZ = 64 ~ 512), or 4 for a resizing range of 1/4 ~ 1/2 (RSZ = 513 ~ 1024). In this way, the upsampling value (L) is fixed to either 8 or 4, and the downsampling value (M) is based on RSZ. To achieve a resizing ratio of 256/RSZ, the downsampling value (M) is equal to (P×RSZ)/256, where P is the number of phases. Figure 12-83 shows the resizer functionality.

**Figure 12-83. Resizer Functionality**

Figure 12-84 shows a model of the resolution of the noninteger downsampling ratio. The interpolated output from the filter is upsampled and replicated 256/P times before it is downsampled by the RSZ factor.

**Figure 12-84. Resizer Approximation Scheme**

This implementation means that a resizing ratio with 256/RSZ times the input size can be obtained. However, each output pixel is rounded to the nearest interpolated output of 1/P input-pixel precision. The polyphase filter coefficients are programmable so that any user-specified filter can be implemented. It is recommended that coefficient sets be chosen to implement a sample rate converter where a low-pass filter is used, with a cutoff frequency as shown in Figure 12-85.

**Figure 12-85. Cutoff Frequency for Low-Pass Filter**

$$\omega_c = \min\left(\frac{\pi}{P}, \frac{\pi}{\left(\frac{P \times RSZ}{256}\right)}\right)$$

camisp-E126

If polyphase resampling is used, all upsampling factors can share the same set of coefficients. However, a different coefficient set is required when changing between 8-phase and 4-phase modes, and with different downsampling factors.

32 programmable coefficients are available for the horizontal direction (registers [RSZ\\_HFILT10](#) to [RSZ\\_HFILT3130](#)) and another 32 programmable coefficients are available for the vertical direction (registers [RSZ\\_VFILT10](#) to [RSZ\\_VFILT3130](#)). The 32 programmable coefficients are arranged as either 4 taps and 8 phases for the resizing range of 1/2 ~ 4 (RSZ = 64 ~ 512), or 7 taps and 4 phases for a resizing range of 1/4 ~ 1/2 (RSZ = 513 ~ 1024)(RSZ is either HRSZ or VRSZ). [Table 12-35](#) shows the arrangement of the 32 filter coefficients. Each tap is arranged in S10Q8 format.

**Table 12-35. Arrangement of the Filter Coefficients**

Filter Coefficient	0.5x to 4x		0.24x to ~0.5x		
	Phase	Tap	Phase	Tap	
0	0	0	0	0	
1		1		1	
2		2		2	
3		3		3	
4	1	0		4	
5		1		5	
6		2		6	
7		3	Not used		
8	2	0	1	0	
9		1		1	
10		2		2	
11		3		3	
12	3	0		4	
13		1		5	
14		2		6	
15		3	Not used		
16	4	0			
17		1			
18		2			
19		3			
20	5	0			
21		1			
22		2			
23		3	Not used		
24	6	0	3		0
25		1			1
26		2			2
27		3		3	
28	7	0			4
29		1			5
30		2			6
31		3	Not used		

The indexing scheme of coefficients is oriented for dot-product (or inner product), rather than for impulse response. In other words, the first data point contributing to a particular output is multiplied by the coefficient associated with tap 0, and the last data point is multiplied by the coefficient associated with tap 3 or tap 6 (depending on whether it is 4-tap or 7-tap mode). The normal raster-scan order is used where the upper-left corner gets the (0, 0) coordinate. Pixel 0 is the left-most column of pixels for horizontal resizing, and the top-most row of pixels for vertical resizing. [Figure 12-86](#) shows an example of the alignment of input pixels to tap coefficients using a simple 1:1 resize case (4-tap mode). In this example, only one phase output is necessary.

[Figure 12-86](#) shows the alignment of input pixels to tap coefficients.

**Figure 12-86. Alignment of Input Pixels to Tap Coefficients**

camisp-116

Figure 12-86 also shows how the first output is computed when all taps are aligned with input pixels. To compute the last several pixels in each line/column, the filter requires more input pixels than the following equation calculates:

$$\text{input size} = \text{output size} * \text{RSZ} / 256$$

In the former example, where the input size is X and the output size is Y, three extra input pixels are required to generate the correct number of output pixels:

$$X = Y * 256 / 256 + 3 \text{ (to account for the extra pixels required for filtering)}$$

The input size calculation depends on the starting phase and rounding issues in the algorithm. Table 12-36 lists the input size calculations derived from the algorithm description in Section 12.4.7.2.5. The input width and height parameters must be programmed strictly according to these equations; otherwise, incorrect hardware operation may occur.

**Table 12-36. Input Size Calculations**

	8-Phase, 4-Tap Mode	4-Phase, 7-Tap Mode
<b>RSZ_IN_SIZE[12:0] HORZ</b>	$(32 * \text{sph} + (\text{ow} - 1) * \text{hrsz} + 16) * 8 + 7$	$(64 * \text{sph} + (\text{ow} - 1) * \text{hrsz} + 32) * 8 + 7$
<b>RSZ_IN_SIZE[28:16] VERT</b>	$(32 * \text{spv} + (\text{oh} - 1) * \text{vrsz} + 16) * 8 + 4$	$(64 * \text{spv} + (\text{oh} - 1) * \text{vrsz} + 32) * 8 + 7$

Where:

sph = Start phase horizontal (**RSZ\_CNT** [22:20] HSTPH)

spv = Start phase vertical (**RSZ\_CNT** [25:23] VSTPH)

ow = Output width (**RSZ\_OUT\_SIZE** [11:0] HORZ + extra)

oh = Output height (**RSZ\_OUT\_SIZE** [27:16] VERT)

hrsz = Horizontal resize value (**RSZ\_CNT** [9:0] HRSZ + 1)

vrsz = Vertical resize value (**RSZ\_CNT** [19:10] VRSZ + 1)

extra = 0 when **RSZ\_YENH** [17:16] ALGO = 0 (edge enhancement disabled)

extra = 4 when **RSZ\_YENH** [17:16] ALGO != 0 (edge enhancement enabled)

The horizontal and vertical starting phases can be programmed in the [RSZ\\_CNT \[22:20\] HSTPH](#) and [RSZ\\_CNT \[25:23\] VSTPH](#) fields, respectively. The chrominance data can be resized using bilinear interpolation or the same algorithm as the luminance data ([RSZ\\_CNT \[29\] CBILIN](#)). For more information about how these fields are used in the algorithm, see [Section 12.4.7.2.5, Resampling Algorithm](#).

### 12.4.7.2.5 Resampling Algorithm

The resizer module uses the same resampling algorithm for the horizontal and vertical directions. For the rest of this section, the horizontal direction is used in describing the resampling algorithm. The algorithm is described first for the 4-tap/8-phase mode, then for the 7-tap/4-phase mode.

[Section 12.4.7.2.5.1](#) and [Section 12.4.7.2.5.2](#) explain the generic algorithm without detailing the differences between color components. [Section 12.4.7.2.5.3](#) describes how interleaved chroma are processed when input is YUV422.

#### 12.4.7.2.5.1 4-Tap/8-Phase Mode

In the 4-tap/8-phase mode, the coefficients for each of the 8 phases may be set to interpolate 8 intermediate pixels between input pixels. For each output pixel calculation, a fine-input pointer with 1/256 input-pixel precision is incremented by the [RSZ\\_CNT \[9:0\] HRSZ + 1](#) value. A coarse-input pointer with 1/8 input-pixel precision (corresponds to one of the 8 phases) is calculated by rounding the fine-input pointer to the nearest 1/8 pixel. The output pixel is calculated by the dot product of the coefficients of the phase filter (selected by the coarse-input pointer) and the appropriate four input pixels. [Figure 12-87](#) shows a pseudo-code description of the resizer algorithm in the 4-tap/8-phase mode.

**Figure 12-87. Pseudo-Code Description of the Resizer Algorithm in the 4-Tap/8-Phase Mode**

camisp-064

- The starting input pixel location (in whole pixels) (see [Section 12.4.7.2.3, Input and Output Interfaces](#)) and the starting phase (in 1/8 pixel) ([RSZ\\_CNT \[22:20\] HSTPH](#)) are programmed through the resizer registers.
- A fine-input pointer is maintained in 1/256-pixel precision.
- A coarse-input pointer and a pixel-input pointer are computed for each output, based on the fine-input pointer.
- The coarse-input pointer is in 1/8 pixel precision. The pixel-input pointer is in whole-pixel precision.
- Initially, fine-input pointer = 256\* starting input pixel + 32\* starting phase - 256. The fine-input pointer defines the starting 1/8 pixel location covered by the filter waveform.
- For each output pixel:

Coarse-input pointer = (fine-input pointer + 16) 5 /\* Rounded to the nearest phase \*/

Pixel-input pointer = (coarse-input pointer 3) + 1 /\* Rounded up to a whole pixel, when already on an integer pixel, go to next one to simplify coefficient organization \*/

Coefficient phase = (coarse-input pointer 7) /\* 3 LSBs = phase \*/

Output = dot product of the 4 coefficients and the 4 inputs starting with pixel-input pointer  
Clip output to 8-bit unsigned for luma, 8-bit signed for chroma

```

fine-input pointer = fine-input pointer
+ (RSZ_CNT [9:0] HRSZ + 1)
/* distance between outputs = 1/resize_factor = (RSZ_CNT [9:0] HRSZ + 1) / 256 = (RSZ_CNT
[9:0] HRSZ + 1) in 1/256 precision */

```

- Same algorithm in the horizontal and vertical directions, except with separate initial pixel/phase values and separate RSZ values.

### 12.4.7.2.5.2 7-Tap/4-Phase Mode

In the 7-tap/4-phase mode, the coefficients for each of the 4 phases may be set to interpolate 4 intermediate pixels between input pixels. For each output pixel calculation, a fine-input pointer with 1/56 input-pixel precision is incremented by the `RSZ_CNT [9:0] HRSZ + 1` value. A coarse-input pointer with 1/2 input-pixel precision (corresponds to one of the 4 phases) is calculated by rounding the fine-input pointer to the nearest 1/2 pixel. The output pixel is calculated by the dot product of the coefficients of the phase filter (selected by the coarse-input pointer) and the appropriate 7 input pixels. Figure 12-88 shows a pseudo-code description of the resizer algorithm in the 7-tap/4-phase mode.

**Figure 12-88. Pseudo-Code Description of the Resizer Algorithm in the 7-Tap/4-Phase Mode**

camisp-065

- The starting input-pixel location (in whole pixels) (see Section 12.4.7.2.3, *Input and Output Interfaces*) and the starting phase (in 1/2 pixel) (`RSZ_CNT [22:20] HSTPH`) are programmed through the resizer registers.
- A fine-input pointer is maintained in 1/256 pixel precision.
- A coarse-input pointer and a pixel-input pointer are computed for each output based on the fine-input pointer.
- The coarse-input pointer is in 1/2 pixel precision. The pixel-input pointer is in whole-pixel precision.
- Initially, fine-input pointer = 256 \* starting input pixel + 64 \* starting phase - 256. The fine-input pointer defines the starting 1/2 pixel location covered by the filter waveform.
- For each output pixel:

```

Coarse-input pointer = (fine-           /* Round to the nearest phase */
input pointer + 32) 6
Pixel-input pointer = (coarse-         /* Round up to a whole pixel; when already on an
input pointer 2) + 1                   integer pixel, go to next one to simplify coefficient
                                       organization */
Coefficient phase = (coarse-          /* 2 LSBs = phase */
input pointer 3)
Output = Dot product of the 7 coefficients and the 7 inputs starting with the pixel-input
pointer
Clip output to 8-bit unsigned for luma, 8-bit signed for chroma
/* It is acceptable to require the 8th coefficients to be filled with zeros by firmware so that 8
coefficients and 8 inputs, the last input being don't care value, are multiply-added */
Fine-input pointer = Fine input pointer + (RSZ_CNT [9:0] HRSZ + 1)
/* Distance between outputs = 1/resize_factor = (RSZ_CNT [9:0] HRSZ + 1)/256 =
(RSZ_CNT [9:0] HRSZ + 1) in 1/256 precision */

```

- Same algorithm in both the horizontal and vertical directions, but with separate initial pixel/phase values and separate RSZ values.

---

**NOTE:** The pixel-input pointer (pip) in the algorithm description, points to pixels, not bytes or shorts in the memory. The fine-input pointer (fip) points to a 1/256 resolution sub-pixel position. The coarse-input point (cip) points to a 1/8 or 1/4 resolution sub-pixel location, depending on the number of phases.

---

### 12.4.7.2.5.3 Horizontal Resizing With Interleaved Chroma

Chroma inputs, Cb and Cr, are 8-bit unsigned values that represent 128-biased 8-bit signed values (the signed chroma are called U and V instead of Cb and Cr). During the resizing computation, the chroma values have the 128 bias subtracted to convert to the 8-bit signed format. After vertical resizing, the 128 bias is added back to convert back to 8-bit unsigned format.

Chroma components, which are 2:1 horizontally downsampled with respect to luma, have two methods of horizontal resizing processing: filtering with luma, and bilinear interpolation.

The horizontal resizing with interleaved chroma option can be selected in the [RSZ\\_CNT](#) [29] CBILIN field independently of the [RSZ\\_CNT](#) [22:20] HSTPH parameters. However, filtering with luma is intended only for downsampling, and bilinear interpolation is intended only for upsampling.

For horizontal resizing of Y/Cb/Cr in a combined filtering flow, the algorithm is modified as shown in the following algorithm descriptions:

#### Filter Chroma With Luma (4-Tap/8-Phase Mode):

```

For (i=0; ioutput_width; i++) { /* output width depends of input width and resizing factors*/
    Coarse-input pointer = (fine-input pointer + 16) 5      /* Round to nearest phase */
    Pixel-input pointer = (coarse-input pointer 3) + 1    /* Round up to a whole pixel */
    Coefficient phase = pixel-input pointer 7            /* 3 LSB = phase */
    if (i 1 == 0) { /* even output pixel, generate YCbCr */
        Yout = dot product of the 4 coefficients and the 4 Y inputs starting with pixel-input pointer
        Cbout = dot product of the 4 coefficients and the 4 upsampled Cb inputs starting with pixel-
        input pointer
        Crout = dot product of the 4 coefficients and the 4 upsampled Cr inputs starting with pixel-
        input pointer
        Clip outputs to 8-bit unsigned for luma, 8-bit
        signed for chroma
    }
    Else { /* odd output pixel, generate Y only */
        Yout = dot product of the 4 coefficients and the 4 Y inputs starting with pixel-input pointer
        Clip output to 8-bit unsigned
    }
    Fine-input pointer = fine-input pointer + (RSZ\_CNT [9:0] HRSZ + 1)
}
}

```

**Filter Chroma With Luma (7-Tap/4-Phase Mode):**

```

For (i=0; ioutput_width; i++) { /* output width depends of input width and resizing factors*/
    Coarse-input pointer = (fine-input pointer + 32) 5      /* Round to nearest phase */
    Pixel-input pointer = (coarse-input pointer 2) + 1    /* Round up to a whole pixel */
    Coefficient phase = pixel-input pointer 3            /* 2 LSB = phase */
    if (i 1 == 0) { /* Even output pixel, generate YCbCr */
        Yout = dot product of the 7 coefficients and the 7 Y inputs starting with pixel-input pointer
        Cbout = dot product of the 7 coefficients and the 7 upsampled Cb inputs starting with pixel-
            input pointer
        Crout = dot product of the 7 coefficients and the 7 upsampled Cr inputs starting with pixel-
            input pointer
        Clip outputs to 8-bit unsigned for luma, 8-bit
            signed for chroma
    }
    Else /* Odd output pixel, generate Y only */
        Yout = dot product of the 7 coefficients and the 7 Y inputs starting with pixel-input pointer
        Clip output to 8-bit unsigned
    }
    Fine-input pointer = fine-input pointer + (RSZ_CNT [9:0] HRSZ + 1)
}
}
    
```

---

**NOTE:** The chroma input values are internally replicated to realize 1:2 upsampling to line up with luma input values. Only required chroma outputs are computed; they correspond to even luma outputs.

---

**Bilinear Interpolation (4-Tap or 7-Tap):**

For the bilinear interpolation flow of chroma horizontal resizing, the algorithm is adapted as follows. For the bilinear interpolation option, it is not necessary to replicate chroma samples.

```

For (i=0; ioutput_width; i++) {
    if (i 1 == 0) { /* even output pixel, generate YCbCr */
        Coarse-input pointer = ... /*Calculation issued from 4 taps or 7
            taps*/
        Pixel-input pointer = ... /*Calculation issued from 4 taps or 7 taps*/
        Yout = dot product of ... /*Calculation issued from 4 taps or 7
            taps*/
        C_fine_input_pointer = fine_input_pointer + 128*ntaps          /* Points to center of filter
            kernel */
        Cidx = C_fine_input_pointer 9                                  /* Truncate to even pixel
            grid to find left value */
        Cbin[0] = Cb[Cidx]
        Cbin[1] = Cb[Cidx + 1]
        Crin[0] = Cr[Cidx]
        Crin[1] = Cr[Cidx + 1]
        frac = C_fine_input_pointer 511                               /* 9-bit fraction */
        Cbout = ((512 - frac) * Cbin[0] + frac * Cbin[1] + 256) 9
    }
}
    
```

```

Crout = ((512 - frac) * Crin[0] + frac * Crin[1] + 256) 9
Clip outputs to 8-bit unsigned for luma, 8-bit signed for chroma
Fine-input pointer = fine-input pointer + (RSZ_CNT [9:0] HRSZ + 1)
}

Else { /* odd output pixel, generate Y only */
    ...
}
}

```

In the former algorithm, fixed-point arithmetic is used. The variable *frac* is an unsigned integer representing the fraction *f*. Thus, 1- *f* becomes 512 - *frac*. After the sum of products, 256, representing 0.5 real-numbers, is added to the sum, and then the sum is right-shifted by 9 bits to get back to the integer chroma representation.

In both algorithm options, the chroma outputs computed are interleaved with luma values to generate the YCbYCr output format (or the alternate format specified in [RSZ\\_CNT \[26\]](#) YCPOS).

In the vertical resizing stage, the two chroma planes are processed interleaved as one separate image. Because there is no resolution issue vertically, and no horizontal dependency in vertical resizing, the vertical scheme is consistent with conventional processing, and is not analyzed here.

#### 12.4.7.2.5.4 Algorithm Functionality

[Table 12-37](#) is an example of 1:2.56 (*hrsz* = 100) horizontal resizing that illustrates the address calculation and chroma processing in 4:2:2 format (4-tap 8-phase mode). The starting pixel and phase are assumed to be zero.

**Table 12-37. Processing Example for 1:2.56 Horizontal Resize**

Output	Y0	Cb0	Cr0	Y1	Y2	Cb2	Cr2	Y3	Y4	Cb4	Cr4	Y5
<b>fip (+= hrsz)</b>	-256		-156		-56		44		144		244	
<b>cip (= (fip+16)5)</b>	-8		-5		-2		1		5		8	
<b>pip (= (cip3) + 1)</b>	0		0		0		1		1		2	
<b>coef ph (= cip 7)</b>	0		3		6		1		5		0	
<b>Inputs needed (chroma filtered like luma)</b>	Y0	Cb0	Cr0	Y0	Y0	Cb0	Cr0	Y1	Y1	Cb0	Cr0	Y2
	Y1	Cb2	Cr0	Y1	Y1	Cb0	Cr0	Y2	Y2	Cb2	Cr2	Y3
	Y2	Cb2	Cr2	Y2	Y2	Cb2	Cr2	Y3	Y3	Cb2	Cr2	Y4
	Y3	Cb2	Cr2	Y3	Y3	Cb2	Cr2	Y4	Y4	Cb4	Cr4	Y5
<b>Cfip (= fip+512)</b>	256				488				720			
<b>Cidx (= Cfip 9)</b>	0				0				1			
<b>Inputs needed for chroma bilinear interpolation</b>	Cb0		Cr0		Cb0		Cr0		Cb2		Cr2	
	Cb2		Cr2		Cb2		Cr2		Cb4		Cr4	

Note the distinction between using {Cb0, Cb0, Cb2, Cb2} and {Cb0, Cb2, Cb2, Cb4} as input to the filter. The 4 filter taps are applied in order, so with the different chroma component repetition, the result is different (even when the coefficient phase is the same).

The *Cidx* of the chroma bilinear interpolation flow points to the chroma sample in linear array order, so *Cidx* = 1 means we Cb2 and Cb4 are being grabbed.

#### 12.4.7.2.6 Luma Edge Enhancement

Edge enhancement can be applied to the horizontally resized luminance component before the output of the horizontal stage is sent to the line memories and the vertical stage. The [RSZ\\_YENH \[17:16\]](#) ALGO parameter can be set to disable edge enhancement, or to select a 3-tap or a 5-tap horizontal high-pass filter (HPF) for luminance enhancement. The edge enhancement algorithm is as follows:

If edge enhancement is selected, the two left-most and two right-most pixels in each line are not outputted to the line memories and the vertical stage. The `RSZ_OUT_SIZE` [11:0] HORZ register is the final output width, up to 1280 pixels when vertical 4-tap mode is used, and up to 640 pixels when vertical 7-tap mode is used. When edge enhancement is enabled, the horizontal resizer output width used to calculate the required input width must be `RSZ_OUT_SIZE` [11:0] HORZ + 4.

---

**NOTE:** Some details of this feature are not available in the public domain,

---

`RSZ_YENH` [7:0] CORE is in U8Q0. `RSZ_YENH` [11:8] SLOP is in U4Q4. `RSZ_YENH` [15:12] GAIN is in U4Q4.

## 12.4.8 Statistics Collection Modules

The statistics-collection modules (SCMs) are the H3A and histogram modules that provide statistics on the incoming images to help designers of camera systems.

### 12.4.8.1 Statistics Collection: H3A

#### 12.4.8.1.1 Features

The H3A module supports control loops for autofocus, auto white balance, and auto exposure by collecting metrics about the imaging/video data. The metrics are used to adjust parameters for processing the imaging/video data. There are two main blocks in the H3A module:

- Autofocus engine (AF):
  - The AF submodule extracts and filters the red, green, and blue data from input image data and provides the accumulation or peaks of the data in a specified region. The specified region is a two-dimensional block of data referred to as a paxel. The AF engine supports the following features:
    - Peak mode in a paxel (a paxel is defined as a two dimensional block of pixels): Accumulate the maximum focus value of each line in a paxel.
    - Accumulation of the maximum focus value of each line in a paxel
    - Accumulation mode
    - Accumulation/sum mode (instead of peak mode): Accumulation of focus value in a paxel
    - Up to 36 paxels/windows in the horizontal direction and up to 128 paxels/windows in the vertical direction
    - Programmable width and height for the paxel/window
    - Programmable red, green, and blue position within a 22 matrix
    - Separate horizontal start for paxel and filtering
    - Programmable vertical line increments within a paxel
    - Parallel IIR filters configured in a dual-biquad configuration with individual coefficients (2 filters with 11 coefficients each)
- Auto exposure and auto white balance engine (AE/AWB)
  - The AE/AWB engine accumulates values and checks for saturated values in a subsampling of the video data. In the case of the AE/AWB, the two-dimensional block of data is referred to as a window. Thus, other than having different names, paxels and windows are essentially the same. However, the numbers, dimensions, and starting positions of AF paxels and AE/AWB windows are programmable separately. AE/AWB supports the following features:
    - Accumulation of clipped pixels along with all nonsaturated pixels
    - Up to 36 horizontal windows/paxel and up to 128 vertical windows/paxel
    - Separate vertical start coordination and height for a black row of paxels different from the remaining color paxels
    - Programmable horizontal and vertical sampling points in a window

---

**NOTE:** Some details of this feature are not available in the public domain.

---

#### 12.4.8.1.2 Autofocus Engine

The autofocus engine works by extracting each red, green, and blue pixel from the video stream and subtracting a fixed offset from the pixel value (128 when A-Law is enabled or 512 when A-Law is disabled). The offset value is then passed through two IIR filters, and the absolute values of the filter outputs are the focus values (FV). For each pixel, the pixel values and the two focus value outputs are accumulated for each color and sent to memory. The following sections describe this process in more detail.

Only RAW10 data is supported by the autofocus function. In some cases, RAW8 or RAW12 data can be converted to RAW10 using the data-lane shifter.

#### 12.4.8.1.3 AE/AWB Engine

The AE/AWB engine starts by dividing the frames into windows and further subsampling each window into 2x2 blocks. Then, for each subsampled 2x2 block, each pixel is accumulated. Also, each pixel is compared to a limit set in a register. If any pixels in a 2x2 block are greater than or equal to the limit, the block is not counted in the unsaturated block counter. Pixels greater than the limit are replaced by the limit, and the value of the pixel is accumulated.

### 12.4.8.2 Statistics Collection: Histogram

#### 12.4.8.2.1 Features

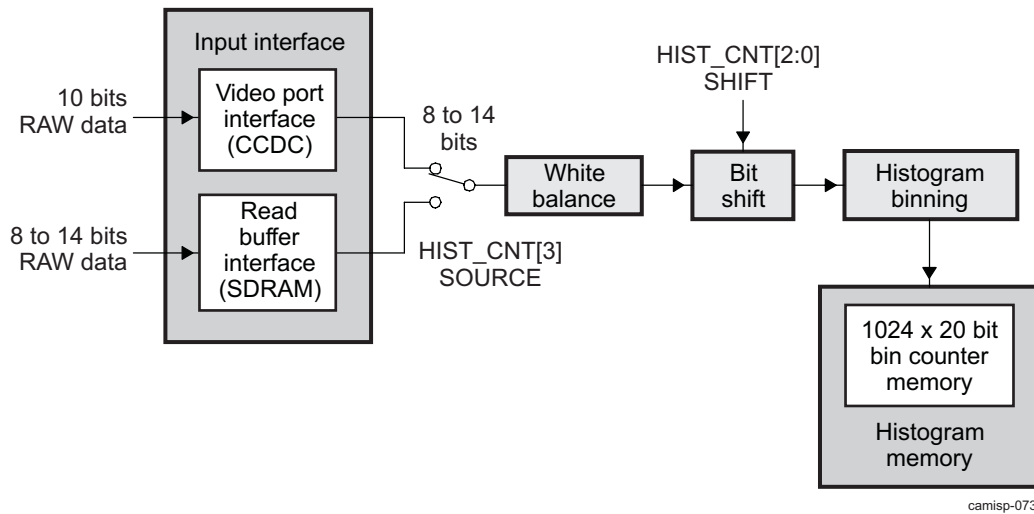

The histogram accepts RAW image/video data from either the video-port interface of the CCDC or from memory, performs a color-separate gain on each pixel (white/channel balance), and bins the pixels according to the amplitude, color, and region specified through the CCDC register settings. It can support 4 colors (Bayer), and up to 4 regions, simultaneously. [Figure 12-89](#) shows the processing of the histogram module.

The histogram module is typically used with 3A metrics by the host processor to adjust various parameters for processing image data. The following features are supported:

- Flexible input: Input data can come from the RAW image sensor (through the CCDC module) or from memory.
- Color-separate gain: A digital gain per color component can be applied before histogram computation.
- Histogram computation: The module performs pixel binning of the incoming RAW image data. Each bin collects the number of pixels with values in a range. If no saturation occurs, the sum of the values in every bin is equal to the total number of pixels in the input image. The histogram computation can occur over one frame or be accumulated over multiple frames. The computation occurs on rectangular regions. A histogram is computed for each color component in the image:
  - The RAW image data dynamic can be up to 10 bits (pixel values in the range 0 to 1023).
  - Range: Each bin covers a pixel range. Each bin can cover a maximum of 128 pixel values.
  - Programmable regions: There can be up to four regions. The region positions and horizontal and vertical sizes are programmable. When regions overlap, pixels from the overlapped area are accumulated into the highest-priority region only; region0 has the highest priority and region3 the lowest priority.
  - Programmable number of bins: There can be 32, 64, 128, or 256 bins per color and per region. The number of bins depends on the number of regions, because histogram memory size is fixed.
  - Color components: A histogram is computed for each color component in the RAW image. There are usually 4 color components in Bayer image sensors.
- Saturation: If the pixel count exceeds  $2^{20}-1$ , the pixel count is saturated.
- Memory clear: The histogram memory is cleared automatically when it is read.
- Output: The histogram result is stored in a local RAM read by a system initiator, typically the system DMA, to be written to memory.

### 12.4.8.2.2 Block Diagram

**Figure 12-89. Histogram Process**

### 12.4.8.2.3 Input Interface

The histogram receives RAW image/video data from the video port interface through the CCDC (which is interfaced to an external sensor) or from the read buffer interface through memory ([HIST\\_CNT \[3\] SOURCE](#)).

The input data is 10 bits wide if the source is the video-port interface. When the input source is from memory, data-bit width can range from 8 to 14 bits. If the input data is 8 bits packed (memory contains two 8-bit pixels for every 16 bits), the [HIST\\_CNT \[8\] DATSIZ](#) bit must be set. If memory contains one pixel for every 16 bits, the DATSIZ bit must be cleared.

Likewise, if memory contains one pixel for every 16 bits, the DATSIZ bit must be cleared. The input memory address ([HIST\\_RADD](#)) and line-offset ([HIST\\_RADD\\_OFF](#)) registers are used to specify the location of the input frame in memory. Both of these registers should be aligned on 32-byte boundaries.

The frame-input width and height are configured using the [HIST\\_H\\_V\\_INFO \[29:16\] HSIZE](#) and [HIST\\_H\\_V\\_INFO \[13:0\] VSIZE](#) register fields, respectively.

The histogram module supports 4-color Bayer color patterns. The [HIST\\_CNT \[6\] CFA](#) field is used to select the color pattern of the input data (Bayer).

### 12.4.8.2.4 White Balance

A white-balance gain can be separately applied to each color channel by programming the fields in the [HIST\\_WB\\_GAIN](#) register. [Table 12-38](#) indicates which pixel index in the color pattern corresponds to each field in the WB\_GAIN register.

**Table 12-38. White Balance Field-to-Pattern Assignments**

<a href="#">HIST_WB_GAIN</a> fields	Bayer
<b>WG00</b>	0
<b>WG01</b>	1
<b>WG02</b>	2
<b>WG03</b>	3

**NOTE:** There are four different physical locations, with one color per location for Bayer. See [Figure 12-90](#).

**Figure 12-90. Color Pattern Index**

Bayer	
0	1
2	3

camisp-309

Each gain constant is 8 bits wide with 5 bits of decimal precision (U8Q5).

**12.4.8.2.5 Histogram Binning**

The histogram bins the input data by amplitude, color, and region (see [Figure 12-91](#)). Each bin is a counter, counting the number of pixels of a color in the range associated with the bin. The number of bins can be programmed to 32, 64, 128, or 256 bins in the `HIST_CNT` [5:4] BINS field. However, due to limited histogram memory size (1024 words), the number of bins (times 4 colors) limits the number of regions that can be active, as shown in [Table 12-39](#).

**Table 12-39. Regions and Bins for Histogram**

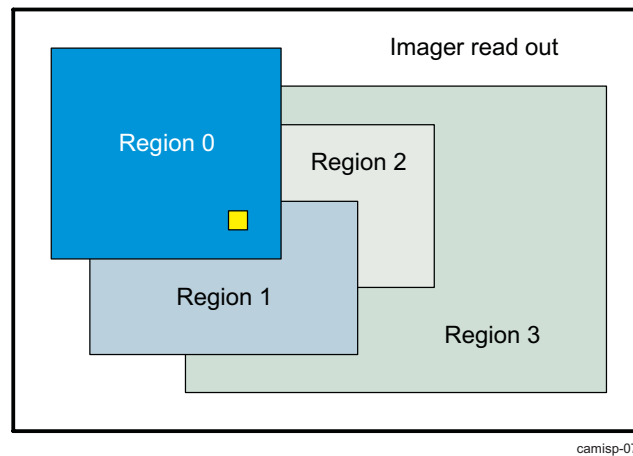

Number of Bins	Number of Regions Allowed
256	1
128	2
64	4
32	4

As indicated by [Table 12-39](#), up to four overlapping regions can be designated within the frame. Each region is defined by the horizontal starting (`HIST_Rn_HORZ` [29:16] HSTART) and ending (`HIST_Rn_HORZ` [13:0] HEND) pixels, and the vertical starting (`HIST_Rn_VERT` [29:16] VSTART) and ending (`HIST_Rn_VERT` [13:0] VEND) lines (where n is the region number 0...3).

**NOTE:** If the starting and ending pixels/lines are the same, the region size is treated as zero, and there is no binning for such a region.

**12.4.8.2.5.1 Region Priority**

Up to four regions can be active at any time, but a pixel is binned into only one region. The priority is Region 0 Region 1 Region 2 Region 3. For example, the yellow pixel in [Figure 12-91](#) is binned only for Region 0, although it is present in all four regions.

**Figure 12-91. Region Priority**

### 12.4.9 Central-Resource Shared Buffer Logic

The central-resource shared buffer logic (SBL) receives data read and write requests from the CCDC, preview, H3A, histogram, resizer, CS1a, and CS1b modules. It arbitrates between requestors and constructs bursts to transfer data to and from memory.

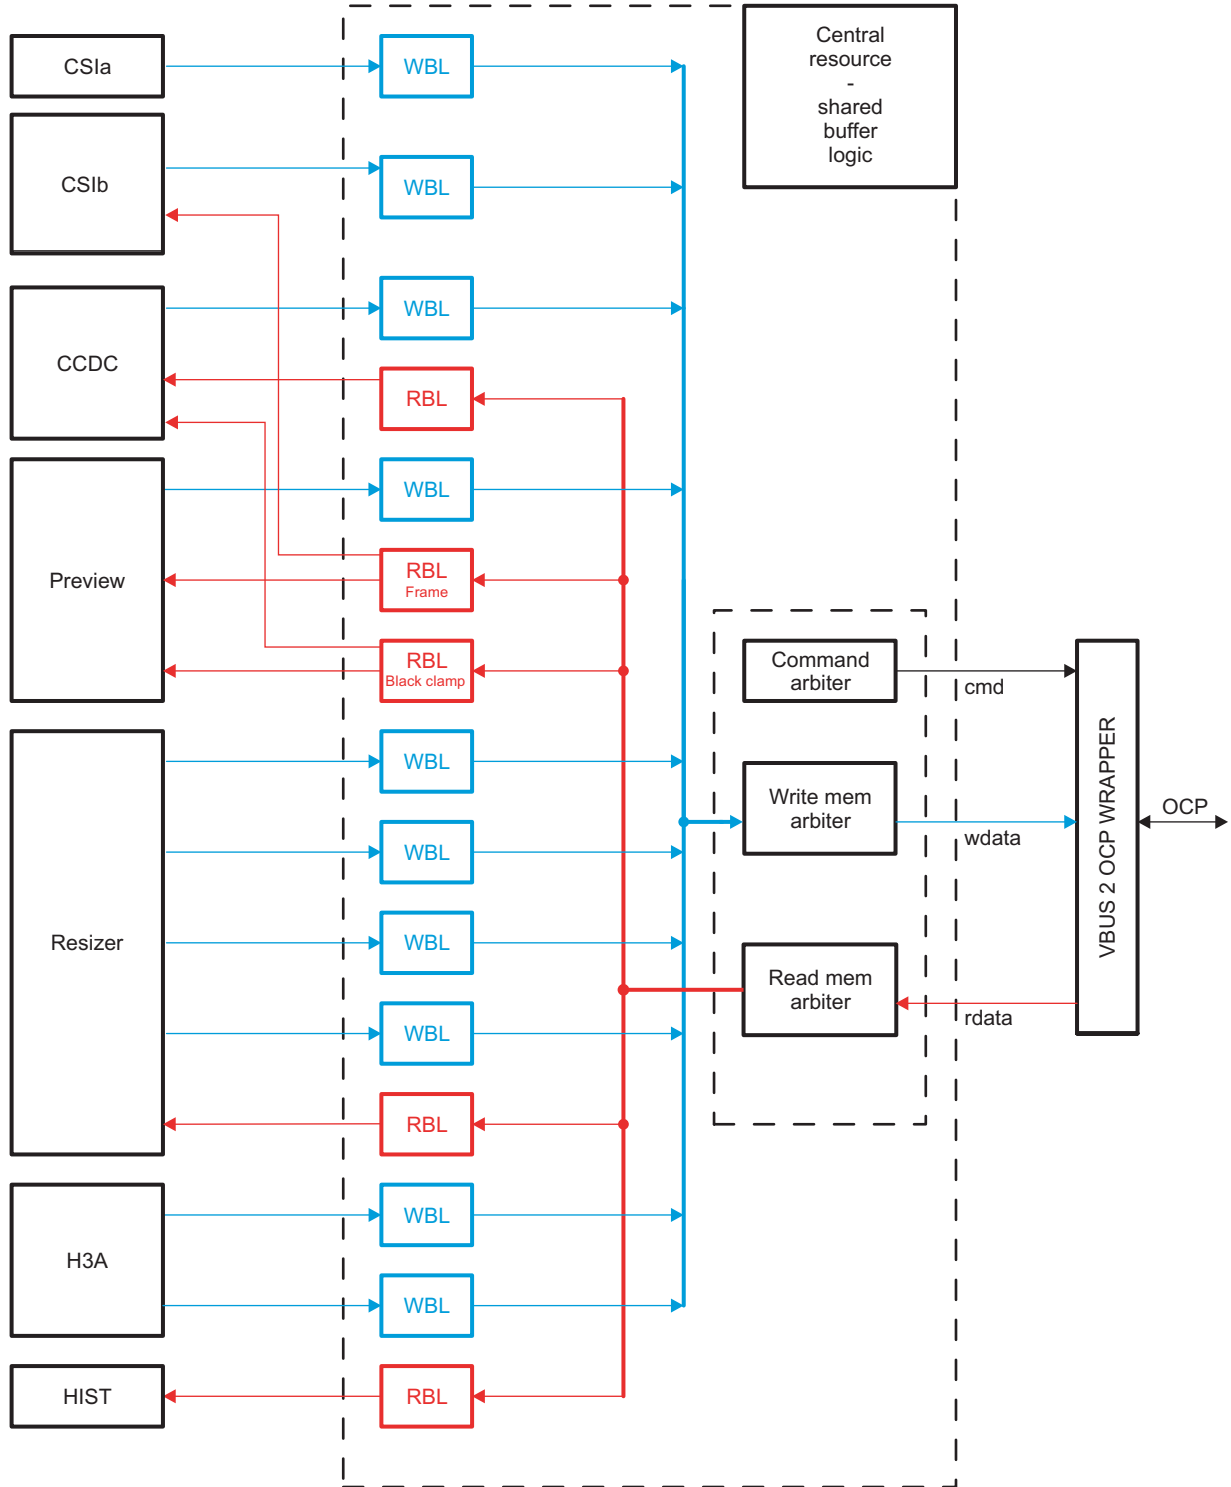

The central-resource SBL performs the following functions:

- Interface to the CCDC module:
  - Collects output data from the CCDC in the write buffer (1 port)
  - Transfers faulty-pixel table data to the CCDC from the read buffer (2 ports)
  - Transfer lens-shading compensation to the CCDC engine from the read buffer. This port is shared with PREVIEW module dark frame subtract port.
- Interface to the CSI receiver modules:
  - Collects output from CS1a in the write buffer (1 port)
  - Collects output from CS1b in the write buffer (1 port)
  - Transfer input data to the CS1b from the read buffer. This port is shared with the PREVIEW module input data read port.
- Interface to the preview module:
  - Collects output data from the preview engine in the write buffer (1 port)
  - Transfer input data to the PREVIEW engine from the read buffer (1 ports). This port is shared with CS1b data read port.
  - Transfer dark frame subtract data to the PREVIEW engine from the read buffer . This port is shared with CCDC lens-shading compensation read port.
- Interface to the H3A module:
  - Collects output data from the H3A in the write buffer (2 ports)
- Interface to the histogram module:
  - Transfers input data to the histogram from the read buffer (1 port)
- Interface to the resizer module:
  - Collects output data from the resizer in the write buffer (4 ports)
  - Transfers input data to the resizer from the read buffer (1 port)
- Requests arbitration between the different initiators. Based on fixed priorities.
- Performs throttle memory read requests for preview, resizer, and histogram to limit bandwidth in memory-to-memory operations

12.4.9.1 Block Diagram

Figure 12-92 shows the central-resource SBL. It comprises WBL and RBL blocks, read and write buffers, and arbitration logic. The VBUSM data-width to the memory is 64 bits.

Figure 12-92. Central-Resource SBL Block Diagram

camisp-078

NOTE: Red = Reads; Blue = Writes

### CAUTION

Because some of the read ports are shared, software must enable the modules that will use the shared read port. For more information, see [Section 12.4.9.2.3, Read Buffer Logic \(RBL\) and Read Buffer](#).

## 12.4.9.2 Functional Operations

### 12.4.9.2.1 Parameters

[Table 12-40](#) summarizes the central-resource SBL parameters. Those parameters are fixed at design time and cannot be changed by users. The functional operations of the central-resource SBL are based on a fixed data size of 256 bytes called a data unit (DU). P0 has the highest priority and P14 has the lowest priority.

**Table 12-40. Central Resource SBL Fixed Parameters**

Port	Port Direction	Port Priority	Buffer Size Bytes	Description
CS1a	WRITE	P3	1024 = 4DUs	CS1a output port
CS1b	WRITE	P2	1024 = 4DUs	CS1b output port
CCDC	WRITE	P4	1024 = 4DUs	CCDC output port
	READ	P1	512 = 2DUs	CCDC fault pixel correction input port
PREVIEW	WRITE	P9	1024 = 4DUs	PREVIEW output port
	READ	P13	1024 = 4DUs	PREVIEW input port CS11 data input port
	READ	P0	1024 = 4DUs	PREVIEW dark-frame input port CCDC lens-shading compensation input port
RESIZER	WRITE	P5	1024 = 4DUs	RESIZER output line 1 port
	WRITE	P6	1024 = 4DUs	RESIZER output line 2 port
	WRITE	P7	1024 = 4DUs	RESIZER output line 3 port
	WRITE	P8	1024 = 4DUs	RESIZER output line 4 port
	READ	P12	1024 = 4DUs	RESIZER input port
H3A	WRITE	P10	512 = 2DUs	H3A output - AF port
	WRITE	P11	512 = 2DUs	H3A output - AE/AWB port
HIST	READ	P14	512 = 2DUs	HIST input port

### 12.4.9.2.2 Write-Buffer Logic (WBL) and Write Buffer

The central-resource SBL uses multiple WBL blocks to interface between the modules' write ports and the write-buffer memory.

- One WBL is instantiated for each module write port.
- Each WBL collects the module's write port output data and transfers the data to the write-buffer memory. Arbitration occurs between the WBL blocks to access the write-buffer memory.
- Each WBL is responsible for tracking all corresponding DUs in the write-buffer memory. There can be 2 or 4 DUs in the write buffer associated with a WBL.
- A WBL generates a command to memory when:
  - The write data crosses a DU boundary. At this point, the module starts filling a new DU. Also, the WBL generates a command to transfer the previous DU to memory.
  - An end-of-frame occurs. The DU (even if not full) is transferred to memory, and a command is issued.
  - An end-of-line occurs. The DU (even if not full) is transferred to the memory, and a command is

issued.

#### 12.4.9.2.3 Read Buffer Logic (RBL) and Read Buffer

The central-resource SBL uses multiple RBL blocks to interface between the modules' read ports and the read-buffer memory.

- One RBL is instantiated for each module read port.
- Each RBL is responsible for accepting input data from the read-buffer memory and for sending the input data to the read port of the corresponding module.
- Each RBL is responsible for tracking all corresponding DUs in the read-buffer memory. There can be 2 or 4 DUs in the read buffer associated with a RBL.
- Unlike the WBL, the RBL is not responsible for issuing the commands to memory; each individual module is responsible for doing this.

Two read ports are shared:

- Between the PREVIEW module dark frame and the CCDC lens-shading compensation input
- Between the PREVIEW module and the CSI1 module data read input

They can only be used by one module at a given time because there is no arbitration mechanism. Software is responsible of enabling only one of the 2 possible features attached to a port and to select the correct multiplexer configuration using the [ISP\\_CTRL \[27\]](#) SBL\_SHARED\_RPORTA and [ISP\\_CTRL \[28\]](#) SBL\_SHARED\_RPORTB registers.

#### 12.4.9.2.4 Arbitration

The central-resource SBL arbitrates between module requests, based on fixed priorities. Read and write requests are arbitrated independently.

A total of 8 commands can be active at a time. When a new slot opens, the highest-priority transfer enters the command queue.

RBLs/WBLs are ensured access to the read/write buffer memories at least once every other cycle.

---

**NOTE:** The hardware uses burst. All bursts are precise; the total number of transfers in the burst is known at the start of the burst. All writes are posted.

---

#### 12.4.9.3 Memories

The central-resource shared-buffer module has three memories:

- READ BUFFER: Shared by all modules
- WRITE BUFFER 0: Used only by the resizer module
- WRITE BUFFER 1: Shared by all modules except RESIZER

#### 12.4.9.4 Debug Registers

Some registers are available for debugging data transfers between a module and external memory. The read-only debug registers are divided into two categories:

- 8 global request registers to capture information about any of the 52 module request registers at a given time. Each register provides information about one DU. The number 16 corresponds to the maximum number of outstanding requests, according to the protocol. Each global request register provides the following information:
  - Individual module register command number. For modules with 2 individual requestors, this field displays either 0 or 1. For modules with 4 individual requestors, this field displays 0, 1, 2, or 3.
  - Source or destination module
  - Data-flow direction
  - Valid bit

- 52 individual module request registers (read or write information). Each register provides information about one DU. The number of request registers assigned (2 or 4) depends on memory bandwidth requirements; modules with lower requirements are assigned 2 request registers, while modules with higher bandwidths are assigned 4 request registers.

**Table 12-41. Central Resource SBL Number of Request Registers**

Port	RD/WR	Nb Request Registers	Description
CS1a	WRITE	4 WR request registers	CS1a output
CS1b	WRITE	4 WR request registers	CS1b output
CCDC	WRITE	4 WR request registers	CCDC output
	READ	2 RD request registers	CCDC fault pixel correction input
PREVIEW	WRITE	4 WR request registers	PREVIEW output
	READ	4 RD request registers	PREVIEW input
	READ	4 RD request registers	PREVIEW dark-frame input
RESIZER	WRITE	4 WR request registers	RESIZER output line 1
	WRITE	4 WR request registers	RESIZER output line 2
	WRITE	4 WR request registers	RESIZER output line 3
	WRITE	4 WR request registers	RESIZER output line 4
	READ	4 RD request registers	RESIZER input port
H3A	WRITE	2 WR request registers	H3A output - AF port
	WRITE	2 WR request registers	H3A output - AE/AWB port
HIST	READ	2 RD request registers	HIST input

Each write-request register provides the following information:

- Current byte count: Number of bytes in the block of data for this command, up to 256 bytes
- Data ready: Block of data confirmed by the module
- Data sent: Data sent to the destination and waiting for status
- Upper 20 bits of the address

Each read-request register provides the following information:

- Valid: Read requested from the module
- Waiting for data: Command accepted from the source
- Data available: Data received from the source and can be read by the module
- Byte count requested: Up to 256 bytes
- Upper 20 bits of the address

### 12.4.10 Circular Buffer

The circular buffer (CBUFF) maps a virtual space to a physical space by address translation. It does not change the data or store it locally.

---

**NOTE:** Addresses can be further translated by the MMU.

---

#### 12.4.10.1 Feature List

The features are listed below:

- Two independent circular buffers (CBUFF0 and CBUFF1)
- Linear address space (virtual) mapped into a circular space (physical)
- Fully transparent for accesses out of the configured virtual space
- Maximum physical buffer size of 16x16M bytes:

- Physical space is composed by 2,4,8 or 16 windows
- Maximum allowed window size is 16M bytes
- Support for multiline write patterns
  - Used together with the resizer in upscale mode. Each buffer must contain at least ceil (vertical zoom factor) images lines
- Support of 2D addressing modes
- Strong error detection mechanisms
- Buffer addresses are 64-bit aligned, but window fill level managing is byte accurate.
- Read and write accesses are supported.
- Bandwidth Control Feedback loop connected to the CSI1 receiver flexible input

#### 12.4.10.2 Interrupts

All events generated (see [Table 12-18](#) for details) by the circular buffer are merged into a single event at camera ISP level. This event can be mapped to MPU SS by enabling the [ISP\\_IRQ0ENABLE](#) [21] CBUFF\_IRQ bit or to IVA2.2 by enabling the [ISP\\_IRQ1ENABLE](#) [21] CBUFF\_IRQ bit.

#### 12.4.10.3 Functional Description

The CBUFF module maps a virtual address space to a physical space called circular buffer. The CBUFF module can handle up to 2 independent circular buffers CBUFF0 and CBUFF1.

This section gives an overview of typical uses of the module.

##### 12.4.10.3.1 Bandwidth Control Feedback Loop

The bandwidth control feedback (BCF) feature can be used in memory to memory operation when the camera ISP reads data through the CS1b receivers flexible input.

At a given time a certain number of physical buffers are available for the processor. Depending, if the circular buffer is configured in read or write mode, the processor can, respectively, write or read those physical buffers.

When the number of physical buffers to be processed by the processor increases, the number of physical buffers available to the camera ISP decreases. When the number of physical buffers available for the camera ISP becomes too low, the corresponding BCF signal is asserted. This signal can be used to stall the data read flow.

The camera ISP supports two mechanisms to reduce the processing speed in memory to memory operation:

- Add a fixed delay between memory read requests. Delays can be added:
  - At SBL level for all image data read ports (histogram, preview, CSI1 and resizer)
  - At CSI1 module level by slowing down the video port clock
- Stall memory reads based on the level of the circular buffer. That is the purpose of the BCF feature described in this section.

##### 12.4.10.3.1.1 Single Slice Mode

The camera ISP writes data with an incremental addressing scheme to the virtual space. The physical buffer is smaller than the virtual space. Therefore, the physical buffer locations is read or written multiple times. See [Figure 12-93](#).

**Figure 12-93. Single Slice Buffer (Write Mode)**

Physically, this circular buffer is typically in the SDRAM. The virtual space is defined by a start and an end address. The physical buffer is defined by a start address, a window size, and a window count. It is contiguous in memory.

Figure 12-94 shows the buffer organization for a 4-window buffer.

**Figure 12-94. Single Slice Buffer Example (Write Mode)**

The CBUFF module can manage two independent circular buffers in single slice mode.

In case of memory-to-memory operation, the module using the data (that is, JPEG CODEC) written by the ISP into the circular buffer may be slower than the camera ISP. That is especially the case when the resizer is used for upscaling.

In this section, it is assumed that the data to be read by the camera ISP is a full frame completely present in physical memory. Sliced buffer capability is only used the buffer data at the output of the camera ISP. Therefore, the circular buffer is configured in write mode.

The basic idea is to stall the read data flow at CS1b flexible input level. This is done by blocking the response phase of the CS1b interconnect read master port. Blocking the response phase rather than the request phase allows data prefetch at SBL level.

When the count of full windows is greater than or equal to the value defined in the `CBUFFx_CTRL[7:4]` BCF register, the data flow between the SBL buffer and the CSI1 data read port is stalled. Data transfers resume when the full window count falls below the defined limit.

Stalling the data flow at this level does not prevent the SBL from fetching data until its buffers are full. Therefore, when data transfer resumes, data are available quickly at the CSI1 read port level, and ISP processing can resume.

Due to SBL buffering, some data may be sent out to the circular buffer when the stall command is activated. Firmware must allocate enough space in the circular buffer to avoid an overflow. The amount of buffered data depends on the ISP configuration:

- The camera ISP pipeline can contain up to 10 pixels that are sent to the SBL after stall control is activated.
- The SBL can store up to four DUs at the output of the PREVIEW module. Therefore, when the circular buffer is filled from the PREVIEW module there must be enough space to store the extra 1K byte of data.
- The data path between the resizer and preview module goes through the SBL and data is internally buffered. The SBL can buffer up to four DUs between the PREVIEW and RESIZER module. In other words, when the input of the PREVIEW module is stalled, the RESIZER receives up to 2K bytes before it stalls.
- The SBL can store up to four DUs for each of the RESIZERs write ports. The count of ports used by the resizer depends on the vertical scaling factor; it uses  $\text{ceil}(\text{vscale})$  ports. Each port writes into one image line and can buffer up to 1K byte.
- Depending on the resizing factor, the next write window may already contain up to three full video lines.

The largest amount of buffering is required when all of the following occur:

- The PREVIEW module is used.
- The RESIZER is used with a rescaling factor of 4x in the horizontal and vertical direction.
- The window size is not a multiple of the vertical up scaling factor.

#### **Example 12-1. Example of 4x Digital Zoom Use:**

This example shows how to calculate the minimum required window count when this feature is used.

It is assumed that the camera ISP reads a VGA RAW8 image from memory, processes it in the preview, and scales it up to 5M pix (2560x1920). The circular buffer is used for temporary storage between the JPEG CODEC and the camera ISP. Each window is configured to contain 8 video lines and the stall command is issued when at least two windows of the circular buffer are full.

Because the circular buffer window size is a multiple of the vertical upscaling factor, the next write window is empty when the stall command is issued. However, up to 1K byte = 512 pixels are stored for each write port of the resizer. This data is written as a 512x4 pixel bloc to the circular buffer by the SBL. Between the PREVIEW and RESIZER up to 1kbyte = 512 pixels are stored. This data expands to a block of 512x4x4 pixels written to the circular buffer by the SBL. In other words, up to 7 lines of the circular buffer may be filled after the stall command is issued. A minimum of four windows must be allocated to avoid an overflow of the circular buffer.

**Example 12-1. Example of 4x Digital Zoom Use: (continued)**

**Figure 12-95. Circular Buffer Control Feedback Loop Example**

camisp-163

The CODEC reads data from the circular buffer and flag windows as done. In this example, the stall command is released when the CODEC has completed processing W0 and W1. The camera ISP resumes writing into W3.

---

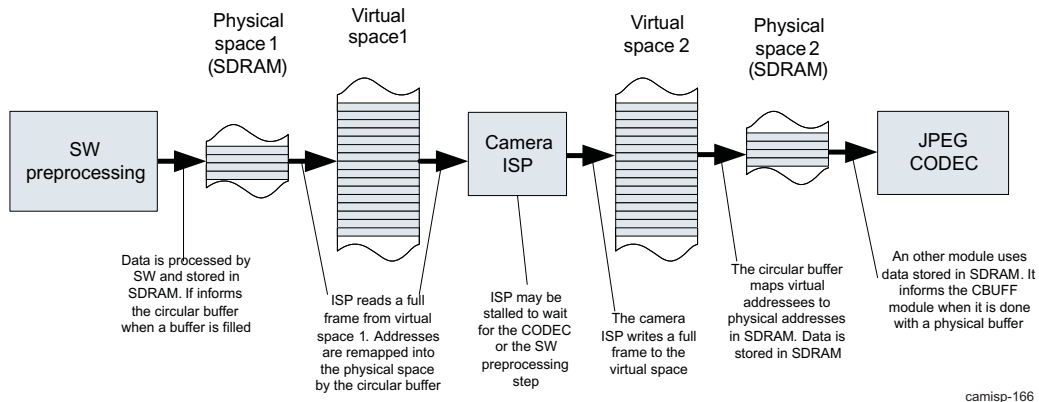

**NOTE:** Software can control the minimum full window count to issue the stall command using the `CBUFFx_CTRL[7:4]` BCF register. Setting this value to 1 or 2 in this example may negatively affect the performance, because only up to two or three windows can be used.

---

**12.4.10.3.1.2 Extended Slice Mode**

In extended slice mode, both circular buffers managed by the CBUFF module are used together. One provides address translation for the read data flow, and the other for a write data flow.

Figure 12-96. Extended Slice Buffer Example

The camera ISP prefetches data and buffers it in the SBL. The CS1b flexible input pre-buffers up to 1K byte of data. In other words, the stall control for the CS1b interconnect read master port must be triggered in advance. Otherwise, the camera ISP may prefetch invalid data.

The last moment when the CS1b interconnect read master port can be safely stalled is when the physical read buffer still contains 1K byte of valid data. The camera ISP may or may not then read the remaining data into its internal SBL buffer.

The minimum amount of buffered data depends on the circular buffer configuration and the used data format.

When the processor filling the read buffer has no more data to write, the BCF feature must be disabled (clear `ISP_CTRL [23:22] CBUFF0_BCF_CTRL` or `ISP_CTRL[25:24] CBUFF1_BCF_CTRL`) for the CBUFF attached to the read data flow. This allows the camera ISP to prefetch the remaining data from the buffer without stalling.

### 12.4.10.3.2 Window Management

This section explains the internal address remapping and windows management algorithm. Internally the module maintains some variables in addition to the configuration registers.

The module manages two circular buffers in parallel. Those are called CBUFF0 and CBUFF1.

Table 12-42. Internal Variables

Quantity	Description
CWx	Current window index for buffer x (x = 0, 1). Possible values are 0 to allowed window count. The current value can be read using the <code>CBUFFx_STATUS[11:8]</code> CW register.
NWx	Next window index for buffer x (x = 0, 1). Possible values are 0 to allowed window count. The current value can be read using the <code>CBUFFx_STATUS[19:16]</code> NW register.
CPUWx	Window in the physical buffer that can be accessed by the CPU. Possible values are 0 to allowed window count. The current value can be read using the <code>CBUFFx_STATUS[3:0]</code> CPUW register.
FCOx	Start address, in the virtual space, of the current window. This is an internal quantity that cannot be accessed by software.
OFFSETy	This is an internal quantity that cannot be accessed by software. y = 0: Address offset used when the current window of buffer 0 is accessed y = 1: Address offset used when the next window of buffer 0 is accessed y = 2: Address offset used when the current window of buffer 1 is accessed y = 3: Address offset used when the next window of buffer 1 is accessed
LEVELy	This is an internal quantity that cannot be accessed by software. y = 0: Amount of data, in bytes, read or written in the current window of buffer 0 y = 1: Amount of data, in bytes, read or written in the next window of buffer 0 y = 2: Amount of data, in bytes, read or written in the current window of buffer 1 y = 3: Amount of data, in bytes, read or written in the next window of buffer 1

### 12.4.10.3.2.1 Startup

The status of a circular buffer (CBUFF0 or CBUFF1) is reset when it is disabled. This does not affect the configuration registers or the [CBUFF\\_IRQSTATUS](#) register. [Table 12-43](#) shows the internal state after reset.

**Table 12-43. Internal State After Reset**

Quantity	Description
CWx	0
NWx	1
CPUWx	0
FCOx	<a href="#">CBUFFx_START</a>
OFFSET0	0
OFFSET1	0
OFFSET2,3	0
LEVELy	0

### 12.4.10.3.2.2 Access Identification

For each access to the virtual space, the CBUFF module first checks the address (ADDR) to classify the transaction into one of the categories listed in [Table 12-44](#).

**Table 12-44. Address Identification**

ID	Label	Condition
0	CW_CBUFF0	<a href="#">CBUFFx_CTRL</a> [0] ENABLE = 1 and ADDR=FCO0 and ADDRFCO0 + <a href="#">CBUFFx_WINDOWSIZE</a> and ADDR= <a href="#">CBUFFx_END</a> (x = 0)
1	NW_CBUFF0	<a href="#">CBUFFx_CTRL</a> [0] ENABLE=1 (x = 0) and ADDR=FCO0 + <a href="#">CBUFFx_WINDOWSIZE</a> and ADDRFCO0 + 2* <a href="#">CBUFFx_WINDOWSIZE</a> and ADDR= <a href="#">CBUFFx_END</a> (x = 0)
2	CW_CBUFF1	<a href="#">CBUFFx_CTRL</a> [0] ENABLE=1 and ADDR=FCO1 and ADDRFCO1 + <a href="#">CBUFFx_WINDOWSIZE</a> and ADDR= <a href="#">CBUFFx_END</a> (x = 1)
3	NW_CBUFF1	<a href="#">CBUFFx_CTRL</a> [0] ENABLE=1 and ADDR=FCO1 + <a href="#">CBUFFx_WINDOWSIZE</a> and ADDRFCO1 + 2* <a href="#">CBUFFx_WINDOWSIZE</a> and ADDR= <a href="#">CBUFFx_END</a> (x = 1)
4	ERR_CBUFF0	<a href="#">CBUFFx_CTRL</a> [0] ENABLE=1 and ADDR= <a href="#">CBUFFx_START</a> and ADDR= <a href="#">CBUFFx_END</a> (x = 0)
5	ERR_CBUFF1	<a href="#">CBUFFx_CTRL</a> [0] ENABLE=1 and ADDR= <a href="#">CBUFFx_START</a> and ADDR= <a href="#">CBUFFx_END</a> (x = 1)
6	TRANSPARENT	Always true

Lower IDs correspond to higher priorities in case multiple conditions are true. For example, when the current virtual window of the circular buffer 0 is accessed, at least the tests for categories CW\_CBUFF0 and ERR\_CBUFF0 are true. The final category is CW\_CBUFF0, because it has a higher priority.

Further processing depends on the category:

- TRANSPARENT: Accesses flow through the module without changing its internal state or any translation.
- ERR\_CBUFF0 and ERR\_CBUFF1: The module goes into error state for the concerned buffer (CBUFF0 or CBUFF1) and set the [CBUFF\\_IRQSTATUS](#)[1] IRQ\_CBUFF0\_INVALID bit (or [CBUFF\\_IRQSTATUS](#)[4] IRQ\_CBUFF1\_INVALID). When the module is in error state for CBUFFx, all

accesses to that buffer are cancelled. In other words, any access that has an address between **CBUFFx\_START** and **CBUFFx\_END** ( $x = 0$ ) is not transmitted to the interconnect. There are two ways to leave the error state:

- Hardware reset
  - Disable and re-enable the buffer (CBUFF0 or CBUFF1) in error state
- Accesses outside of the virtual space from the circular buffer in error state are not affected.

- **CW\_CBUFF0, NW\_CBUFF0, CW\_CBUFF1 and NW\_CBUFF1:** The internal state is updated and address translation is performed when the performed access type (read or write) is compatible with the current mode (read or write). Otherwise, an **IRQ\_CBUFFx\_INVALID** event is set and CBUFFx goes into the error state.

#### 12.4.10.3.2.3 Address Translation

An offset is selected depending on the access category (see [Section 12.4.10.3.2.1, Startup](#)) and the internal state of the accessed buffer. [Table 12-45](#) lists possible cases.

**Table 12-45. Address Translation**

Condition	Address Translation
<b>CBUFFx_CTRL[0] ENABLE=1 and ADDR= CBUFFx_START and ADDR= CBUFFx_END and CBUFF0 in error state (<math>x = 0</math>)</b>	Access cancelled
<b>CBUFFx_CTRL[0] ENABLE=1 and ADDR= CBUFFx_START and ADDR= CBUFFx_END and CBUFF1 in error state (<math>x = 1</math>)</b>	Access cancelled
Category = CW_CBUFF0	ADDRROUT = ADDRIN-OFFSET0
Category = NW_CBUFF0	ADDRROUT = ADDRIN-OFFSET1
Category = CW_CBUFF1	ADDRROUT = ADDRIN-OFFSET2
Category = NW_CBUFF1	ADDRROUT = ADDRIN-OFFSET3
Category = ERR_CBUFF0	Access cancelled
Category = ERR_CBUFF1	Access cancelled
Category = TRANSPARENT	ADDRROUT = ADDRIN

#### 12.4.10.3.2.4 Window Fill Level

Each time an access is performed into an active window (CW\_CBUFF0, NW\_CBUFF0, CW\_CBUFF1 or NW\_CBUFF1) the window level is updated. The corresponding LEVELy is incremented according to the BYTEEN input of the interconnect port. All possible BYTEEN patterns are supported. [Table 12-46](#) shows some examples. The basic idea is to count the number of ones in the BYTEEN input.

**Table 12-46. Window Level Increment**

BYTEEN	LEVELy Increment	Comment
0x00	+0	No access
0x01	+1	8 bit access
0x02	+1	8 bit access
0x03	+2	16 bit access
...	...	...
0x07	+3	24 bit access
...	...	...
0x0F	+4	32 bit access
...	...	...
0xF0	+4	32 bit access
...	...	...

**Table 12-46. Window Level Increment (continued)**

BYTEEN	LEVELy Increment	Comment
0xFF	+8	64 bit access

The window level is compared to [CBUFFx\\_THRESHOLD](#). As listed in [Table 12-47](#), the following situations may occur:

**Table 12-47. Window Level Comparison**

Condition	Description
LEVEL0= <a href="#">CBUFFx_THRESHOLD</a> (x = 0)	Current window of buffer 0 full. Internal window indexes, levels, and offsets are updated.
LEVEL1= <a href="#">CBUFFx_THRESHOLD</a> (x = 0)	Next window of buffer 0 full. An <a href="#">IRQ_CBUFF0_INVALID</a> error event is set and <a href="#">CBUFF0</a> enters the error state.
LEVEL2= <a href="#">CBUFFx_THRESHOLD</a> (x = 1)	Current window of buffer 1 full
LEVEL3= <a href="#">CBUFFx_THRESHOLD</a> (x = 1)	Next window of buffer 1 full. An <a href="#">IRQ_CBUFF1_INVALID</a> error event is set and <a href="#">CBUFF1</a> enters the error state.

#### 12.4.10.3.2.5 Window Pointer and Offset Update

When the current window of a circular buffer ([CBUFFx](#), x = 0 or 1) is full:

- The "next window" becomes the "current window"
  - $CW_x - NW$
  - $LEVEL(2*x) - LEVEL(2*x+1)$
  - $OFFSET(2*x) - OFFSET(2*x+1)$
  - $FCO_x - FCO_x + \text{CBUFFx\_WINDOWSIZE}$
- A new "next window" if opened. The update is done in a circular manner: the first window in the physical space is reused after the last one
  - $NW - (NW+1) \text{ modulo } WC$
  - $LEVEL(2*x+1) - 0$
  - When the "next window" is moved from the last buffer to the first:
    - $OFFSET(2*x+1) - OFFSET(2*x+1) + WC_x * \text{CBUFFx\_WINDOWSIZE}$

---

**NOTE:** WC is the window count defined by the [CBUFFx\\_CTRL\[9:8\]](#) WCOUNT register.

---

#### 12.4.10.3.3 CPU Interaction

The [CBUFF](#) module sets an [IRQ\\_CBUFFx\\_READY](#) event to inform the CPU that it can access the CPUx window in the physical buffer. The [CBUFF](#) module cannot monitor CPU accesses to the physical buffer. The CPU must indicate when it has completed the processing of the CPUWx window by writing the [CBUFFx\\_CTRL\[2\]](#) DONE bit. This increments the CPU window index CPUWx by one modulo the window count.

The behavior depends on whether read or write mode has been selected using the [CBUFFx\\_CTRL\[1\]](#) RWMODE bit.

---

**NOTE:** Some details of this feature are not available in the public domain.

---

## 12.4.11 MMU Logic

### 12.4.11.1 MMU Features

The camera ISP MMU contains a translation lookaside buffer (TLB) that holds translations and properties for current pages. This TLB can be managed statically through the configuration slave port, or by the internal hardware table-walking logic (TWL), which can autonomously traverse the page table on a TLB miss. The TWL can be enabled or disabled (MMU\_CNTL [2] TWLENABLE).

On a TLB miss, the initiator is stalled until a valid address translation is found. If no valid translation is found, a translation fault interrupt is generated to the processor. It is a nonrecoverable situation, which leads to the camera ISP being reset by the processor software.

The MMU provides up to 4G bytes of virtual memory.

### 12.4.11.2 MMU Functional Description

For a detailed description of the MMU, see [Chapter 8, Memory Management Units](#).

---

**NOTE:** In the camera ISP MMU, the endianness feature is available for write, but conversion for read is not possible.

---

## 12.5 Camera ISP Basic Programming Model

### 12.5.1 Programming the CSI1 or CSI2 Receiver Associated Complex I/O

#### 12.5.1.1 Camera ISP Complex I/O Initialization for Work With CSI2 Receiver

To fully initialize the CSI2 complex I/O, perform the following steps:

1. Configure all CSI2 receiver registers to be ready to receive signals/data from the CSI2 complex I/O:
  - (a) Configure all necessary CSI2 registers:
    - (i) Set `CSI2_COMPLEXIO_CFG1[10:8]` DATA2\_POSITION.
    - (ii) Set `CSI2_COMPLEXIO_CFG1[6:4]` DATA1\_POSITION.
    - (iii) Set `CSI2_COMPLEXIO_CFG1[2:0]` CLOCK\_POSITION.

**CAUTION**

This must be done before CSIPHY is active.

2. CSI2 complex I/O and link initialization sequence:
  - (a) Deassert the complex I/O:
    - `CSI2_TIMING[15]` FORCE\_RX\_MODE\_IO1
  - (b) Check whether CSI2 complex I/O reset is done or is ongoing:
    - `CSI2_COMPLEXIO_CFG1[29]` RESET\_DONE = 0x1
  - (c) The following registers can be set only after the complex I/O is reset, and before asserting the ForceRxMode signal:
    - `CSI2PHY_CFG0`
    - `CSI2PHY_CFG1`
  - (d) Assert the ForceRxMode signal:
    - (i) Set `CSI2_TIMING[15]` FORCE\_RX\_MODE\_IO1 to 0x1.
  - (e) Connect the pulldown on the link (DP/DN) by asserting the respective PIPD\* signals (PIPD\* = 0):
    - For CSI1 complex I/O: Pull down on signals through padconf registers:
      - cam\_d6:
        - `CONTROL_PADCONF_CAM_D5[24]` INPUTENABLE1 = 0x1
        - `CONTROL_PADCONF_CAM_D5[20]` PULLTYPESELECT1 = 0x0
        - `CONTROL_PADCONF_CAM_D5[19]` PULLUDENABLE1 = 0x1
      - cam\_d7:
        - `CONTROL_PADCONF_CAM_D7[8]` INPUTENABLE0 = 0x1
        - `CONTROL_PADCONF_CAM_D7[4]` PULLTYPESELECT0 = 0x0
        - `CONTROL_PADCONF_CAM_D7[3]` PULLUDENABLE0 = 0x1
      - cam\_d8:
        - `CONTROL_PADCONF_CAM_D7[24]` INPUTENABLE1 = 0x1
        - `CONTROL_PADCONF_CAM_D7[20]` PULLTYPESELECT1 = 0x0
        - `CONTROL_PADCONF_CAM_D7[19]` PULLUDENABLE1 = 0x1
      - cam\_d9:
        - `CONTROL_PADCONF_CAM_D9[8]` INPUTENABLE0 = 0x1
        - `CONTROL_PADCONF_CAM_D9[4]` PULLTYPESELECT0 = 0x0
        - `CONTROL_PADCONF_CAM_D9[3]` PULLUDENABLE0 = 0x1
    - For CSIPHY2: Pull down on signals through padconf registers:

- cam\_d0:
  - CONTROL\_PADCONF\_CAM\_FLD[24] INPUTENABLE1 = 0x1
  - CONTROL\_PADCONF\_CAM\_FLD[20] PULLTYPESELECT1 = 0x0
  - CONTROL\_PADCONF\_CAM\_FLD[19] PULLUDENABLE1 = 0x1
- cam\_d1:
  - CONTROL\_PADCONF\_CAM\_D1[8] INPUTENABLE0 = 0x1
  - CONTROL\_PADCONF\_CAM\_D1[4] PULLTYPESELECT0 = 0x0
  - CONTROL\_PADCONF\_CAM\_D1[3] PULLUDENABLE0 = 0x1
- csi2\_dx0:
  - CONTROL\_PADCONF\_CSI2\_DX0[8] INPUTENABLE0 = 0x1
  - CONTROL\_PADCONF\_CSI2\_DX0[4] PULLTYPESELECT0 = 0x0
  - CONTROL\_PADCONF\_CSI2\_DX0[3] PULLUDENABLE0 = 0x1
- csi2\_dy0:
  - CONTROL\_PADCONF\_CSI2\_DX0[24] INPUTENABLE1 = 0x1
  - CONTROL\_PADCONF\_CSI2\_DX0[20] PULLTYPESELECT1 = 0x0
  - CONTROL\_PADCONF\_CSI2\_DX0[19] PULLUDENABLE1 = 0x1
- csi2\_dx1:
  - CONTROL\_PADCONF\_CSI2\_DX1[8] INPUTENABLE0 = 0x1
  - CONTROL\_PADCONF\_CSI2\_DX1[4] PULLTYPESELECT0 = 0x0
  - CONTROL\_PADCONF\_CSI2\_DX1[3] PULLUDENABLE0 = 0x1
- csi2\_dy1:
  - CONTROL\_PADCONF\_CSI2\_DX1[24] INPUTENABLE1 = 0x1
  - CONTROL\_PADCONF\_CSI2\_DX1[20] PULLTYPESELECT1 = 0x0
  - CONTROL\_PADCONF\_CSI2\_DX1[19] PULLUDENABLE1 = 0x1
- (f) Power up CSIPHY:
  - (i) Set [CSI2\\_COMPLEXIO\\_CFG1](#)[28:27] PWR\_CMD to 0x1.
- (g) Check that the state status reaches the ON state:
  - [CSI2\\_COMPLEXIO\\_CFG1](#)[26:25] PWR\_STATUS = 0x1
- (h) Wait for STOPSTATE = 1 (for all enabled lane modules):
  - (i) The timer is set through the [CSI2\\_TIMING](#)[14:0] bit field. The reset value can be kept.
  - (ii) Wait until [CSI2\\_TIMING](#)[15] FORCE\_RX\_MODE\_IO1 = 0x0. It is automatically set at 0 when all enabled lanes are in STOPSTATE and the timer is finished.
- (i) Release PIPD\* ( = 1).
  - For CSI1 complex I/O: Pull up on signals through padconf registers:
    - cam\_d6:
      - CONTROL\_PADCONF\_CAM\_D5[20] PULLTYPESELECT1 = 0x1
    - cam\_d7:
      - CONTROL\_PADCONF\_CAM\_D7[4] PULLTYPESELECT0 = 0x1
    - cam\_d8:
      - CONTROL\_PADCONF\_CAM\_D7[20] PULLTYPESELECT1 = 0x1
    - cam\_d9:
      - CONTROL\_PADCONF\_CAM\_D9[4] PULLTYPESELECT0 = 0x1
  - For CSI2 complex I/O: Pull up on signals through padconf registers:
    - cam\_d0:
      - CONTROL\_PADCONF\_CAM\_FLD[20] PULLTYPESELECT1 = 0x1
    - cam\_d1:

- CONTROL\_PADCONF\_CAM\_D1[4] PULLTYPESELECT0 = 0x1
  - csi2\_dx0:
    - CONTROL\_PADCONF\_CSI2\_DX0[4] PULLTYPESELECT0 = 0x1
  - csi2\_dy0:
    - CONTROL\_PADCONF\_CSI2\_DX0[20] PULLTYPESELECT1 = 0x1
  - csi2\_dx1:
    - CONTROL\_PADCONF\_CSI2\_DX1[4] PULLTYPESELECT0 = 0x1
  - csi2\_dy1:
    - CONTROL\_PADCONF\_CSI2\_DX1[20] PULLTYPESELECT1 = 0x1
- (j) Complex I/O is initialized and ready/active in CSI2 mode.

### 12.5.1.2 Camera ISP Complex I/O Initialization for Work With CSI1 Receiver

To fully initialize the complex I/O, perform the following steps:

1. Configure all CSI1 receiver registers to receive signals/data from the complex I/O:
  - (a) Configure the CSI1 receiver mode.
    - (i) Set CONTROL\_CSIRXFE.

#### **CAUTION**

This must be done before the complex I/O is active.

2. CSI1 and link initialization sequence:
  - (a) Reset the complex I/O:
    - (i) Set CONTROL\_CSIRXFE[13] CSIB\_RESET to 0x1.
  - (b) Power up the complex I/O:
    - (i) Set CONTROL\_CSIRXFE[12] CSIB\_PWRDNZ to 0x1.
  - (c) Complex I/O is initialized and ready/active in CSI1 mode.

## 12.5.2 Programming the CSI1 Receiver

This section describes the programming model of the CSI1 receiver.

### 12.5.2.1 Hardware Setup/Initialization

This section discusses the configuration of the CSI1 receiver required before image capture can begin.

#### 12.5.2.1.1 Reset Behavior

On hardware or software reset of the camera ISP, all registers in the CSI1 receiver are reset to their reset values.

#### 12.5.2.2 Event and Status Checking

When an event occurs, the corresponding bit in the CSI1\_IRQSTATUS register is set. Each event can be individually masked using the CSI1\_IRQENABLE register. Masked events are not transmitted to the interrupt lane, but the CSI1\_IRQSTATUS register is updated.

Events transmitted to the interrupt lane can be mapped to the ARM or DSP by unmasking the ISP\_CSIB bit in the ISP\_IRQxENABLE (x = 0, 1). Depending on whether the event is mapped to the ARM or DSP register, to clear an event, the following actions are required:

- Clear the event at the CSI1 receiver level by writing 1 to the corresponding bit in the CSI1\_IRQSTATUS register.

- Clear the event at ISP level by writing 1 to the corresponding bit ISP\_CSIB in the ISP\_IRQxENABLE (x = 0, 1) register.

### 12.5.2.3 Register Accessibility During Frame Processing

There are two types of register accesses in the CSI1 receiver:

- Shadowed registers:
  - These registers/fields can be read and written (if the field is writable) at any time. However, written values take effect only at the start of a frame. Reads return the most recent write, even though the settings are not used until the next start of frame.
  - The shadowed registers are:
    - CSI1\_CTRL1
    - CSI1\_CODE
    - CSI1\_STAT\_START
    - CSI1\_STAT\_SIZE
    - CSI1\_SOF\_ADDR
    - CSI1\_EOF\_ADDR
    - CSI1\_DAT\_SIZE
    - CSI1\_DAT\_PING\_ADDR
    - CSI1\_DAT\_PONG\_ADDR
    - CSI1\_DAT\_OFST
- Busy-locked registers:
  - These registers/fields must not be written if the module is busy.
  - All register fields not listed as shadowed are busy-writable registers.

### 12.5.2.4 Enable/Disable the Hardware

The CSI1 receiver is globally controlled by the CSI1\_CTRL register. The bit fields in this register must not be modified when the CSI1 interface is active (except CSI1\_CTRL [0] IF\_EN):

- To activate the CSI1 interface:
  - CSI1\_CTRL [0] IF\_EN = 0x1
  - Data acquisition starts on the following FSC synchronization code. Writing CSI1\_CTRL [0] IF\_EN = 0x1 resets the output FIFO of the module; the reset is caused by the 0-to-1 edge transition.
- To disable the CSI1 interface:
  - CSI1\_CTRL [0] IF\_EN = 0x0
  - The interface is disabled immediately if CSI1\_CTRL [3] FRAME = 0x0.
  - If CSI1\_CTRL [3] FRAME = 0x1 the interface is disabled after the FEC synchronization code is received.

### 12.5.2.5 Complex I/O Control

#### CAUTION

When using the CS1b receiver, the CONTROL.CONTROL\_CSIRXFE[12] CS1b\_PWRDN bit must be set to 1 to enable the transceiver, and the CONTROL.CONTROL\_CSIRXFE[13] CS1b\_RESET bit must be set to 1 to disable the reset before starting the transfer.

The CSI1\_CTRL [2] IO\_OUT\_SEL bit selects the output mode of the CSI1 complex I/O cell, which can be serial or parallel. Frame-shift errors are not detected when parallel mode is selected.

The CSI1\_CTRL [10] INV bit selects the clock edge used to sample data:

- If CSI1\_CTRL [10] INV = 0x0, use the rising edge.
- If CSI1\_CTRL [10] INV = 0x1, use the falling edge.
- The polarity is changed only if the SCM-associated bit is also changed: CONTROL.CONTROL\_CSIRXFE CSIx\_INV.

### 12.5.2.6 Debug Mode

Use the CSI1\_CTRL [7] DBG\_EN bit to enable the debug mode:

- During debug mode, the input comes from the CSI1\_DBG register, not from the CSI1 physical interface. The full CSI1 receiver functionality can be debugged in debug mode. Full 32-bit values must always be written to the CSI1\_DBG register.
- The following bits have no effect during debug mode:
  - CSI1\_CTRL [0] IF\_EN
  - CSI1\_CTRL [1] PHY\_SEL
  - CSI1\_CTRL [2] IO\_OUT\_SEL
- The following examples apply to the CSI1\_DBG register:
  - Synchronization codes: CSI1\_DBG = 0xFF000000
  - To send the RAW12 pixels 0x673, 0x452, 0x01d, 0xefc, 0xab0, 0x891, 0x326, and 0x547, write CSI1\_DBG = 0x01234567 followed by CSI1\_DBG = and 0x89abcdef CSI1\_DBG = 0x76543210.

---

**NOTE:** Each write to the CSI1\_DBG register sends a full 32-bit word through the CSI1 receiver hardware. When 8- or 16-bit writes are performed to the register, the previous 32-bit value is merged with the newly written one. When the driver writes, for example, 0x01234567 followed by 0x000000FF with BYTEEN = 0x1 (this write from the MPU subsystem informs that only 8 bits are written), the CSI1 receiver pipeline gets 0x01234567 followed by 0x012345FF.

---

### 12.5.2.7 Video Port

- Set the video-port output frequency:
  - CSI1\_CTRL [9:8] VP\_OUT\_CTRL
  - The video-port output frequency varies from CAM\_ICLK to CAM\_ICLK/4 MHz. CAM\_ICLK is the CSI1 receiver functional and interface clock. The reset value selects CAM\_ICLK/2.
- CSI1\_CTRL [11] VP\_ONLY\_EN:
  - Controls whether the video-port output is the only output interface enabled and applies for all channels.
  - When CSI1\_CTRL [11] VP\_ONLY\_EN = 0x1, the data are output only to the video port; the interface master port is not used. The two parts of the frame (embedded data and pixel data) are output to the video port (instead of pixel data to video port and embedded data to interconnect).
    - The video port outputs the embedded data defined by the CSI1\_STAT\_START and CSI1\_STAT\_SIZE registers without decompression.
    - The video port outputs the pixel data defined by the CSI1\_DAT\_START and CSI1\_DAT\_SIZE registers.
  - The pixel data are decompressed according to the settings of the CSI1\_CTRL1 [7:3] FORMAT bit field. [Table 12-48](#) summarizes the behavior of the video port as a function of the CSI1\_CTRL [7:3] FORMAT bit field.

**Table 12-48. CSI1\_CTRL1 [7:3] FORMAT and CSI1\_CTRL [11] VP\_ONLY\_EN = 1 Settings**

CSI1_CTRL1 [7:3] Format	Video-Port Behavior
YUV422 + VP or RAW8 + VP	The incoming data are 8 bits. The pixel data are not compressed. The embedded data are transmitted to the CCDC module on 8 bits (DATA[7:0]). The pixel data are not decompressed. The pixel data are transmitted to the CCDC module on 8 bits (DATA[7:0]).
RAW12 + VP	The incoming data are 12 bits. The pixel data are not compressed. The embedded data are transmitted to the CCDC module on 12 bits (DATA[11:0]). The pixel data are reconstructed in the receiver. The pixel data are transmitted to the CCDC module on 12 bits (DATA[11:0]). The pixel data are not decompressed.

- Control the video-port pixel clock polarity:
  - If CSI1\_CTRL [12] VP\_CLK\_POL = 0x0, the CSI1 receiver module writes the data on the video port on the pixel-clock falling edge. The module connected to the VP samples the data on the pixel clock rising edge.
  - If CSI1\_CTRL [12] VP\_CLK\_POL = 0x1, the CSI1 receiver module writes the data on the video port on the pixel-clock raising edge. The module connected to the VP samples the data on the pixel clock falling edge. [Figure 12-97](#) shows the CSI1\_CTRL.VP\_CLK\_POL settings.

**Figure 12-97. CSI1\_CTRL.VP\_CLK\_POL Settings**

### 12.5.2.8 Region of Interest

The CSI1\_CTRL1 [1] REGION\_EN bit enables the region-of-interest feature (SOF lines, pixel data, and EOF lines):

- If enabled, register settings set the position and size of each region; all data not in a region of interest are ignored.
- If disabled, all data in the frame are output. CSI1\_CTRL1 [1] REGION\_EN is set to 0x0 for a JPEG bitstream.

### 12.5.2.9 Destination Format

- Control the destination format:
  - The CSI1 receiver reformats received data to store it in memory or to send it to the video-preprocessing.
  - CSI1\_CTRL [7:3] FORMAT controls destination-data format:
    - EXP8 = Data expansion to 8 bits, padding with zeros
    - EXP16 = Data expansion to 16 bits, padding with alpha or zeros CSI1\_CTRL [15:8] ALPHA can be used to set an alpha value. For RGB444 + EXP16:
      - data\_out [31:28] = ALPHA [3:0]
      - data\_out [15:12] = ALPHA [3:0]
    - EXP32 = Data expansion to 32 bits, padding with alpha. CSI1\_CTRL [15:8] ALPHA can be used to set an alpha value. For RGB888 + EXP32: data\_out [31:24] = ALPHA [7:0]
    - FSP = False synchronization code protection decoding. Applies only to JPEG8 data format.
    - VP = Output to the video-preprocessing is enabled.

### 12.5.2.10 Frame Acquisition

- Program the number of frames that the CSI1 receiver acquires:
  - CSI1\_CTRL1 [31:24] COUNT

- Writes to the COUNT bit field are controlled by the CSI1\_CTRL1 [16] COUNT\_UNLOCK bit.
- If COUNT = 0x0, the counter is free-running; frame acquisition lasts until disabled by the programmer. It is the default value.
- COUNT controls the number of frames to acquire. The values range between 1 and 255. The COUNT value is decremented after each frame received. The software can read this value to acquire the number of frames that remain to be acquired.

After the correct number of frames is received, acquisition is automatically disabled ( CSI1\_CTRL1 [0] CHAN\_EN = 0x0) and the COUNT\_IRQ interrupt is triggered. The programmer can reenale the acquisition by resetting CSI1\_CTRL1 [0] CHAN\_EN to 0x1.

CSI1\_CTRL1 [17] PING\_PONG indicates whether the PING address ( CSI1\_DAT\_PING\_ADDR ) or PONG address ( CSI1\_DAT\_PONG\_ADDR ) was used to store the pixel data of the last frame. After reset or after a 0-to-1 edge transition in CSI1\_CTRL [0] IF\_EN, the pixel data are written in the PING buffer and CSI1\_CTRL1 [17] PING\_PONG = 0x1 (PONG). After the first FEC synchronization code is received, the pixel data are written in the PONG buffer and CSI1\_CTRL1 [17] PING\_PONG = 0x0 (PING). CSI1\_CTRL1 [17] PING\_PONG toggles after every FEC synchronization code.

### 12.5.2.11 Synchronization Codes

The CSI1\_CODE register enables overwriting of the default values: CSI1\_CODE [11:8] FSC, CSI1\_CODE [15:12] FEC, CSI1\_CODE [3:0] LSC, and CSI1\_CODE [7:4] LEC overwrite the 4 LSBs of the 32-bit synchronization codes. The default values should not be modified.

### 12.5.2.12 Status Data

The SOF and EOF status lines can be output to memory.

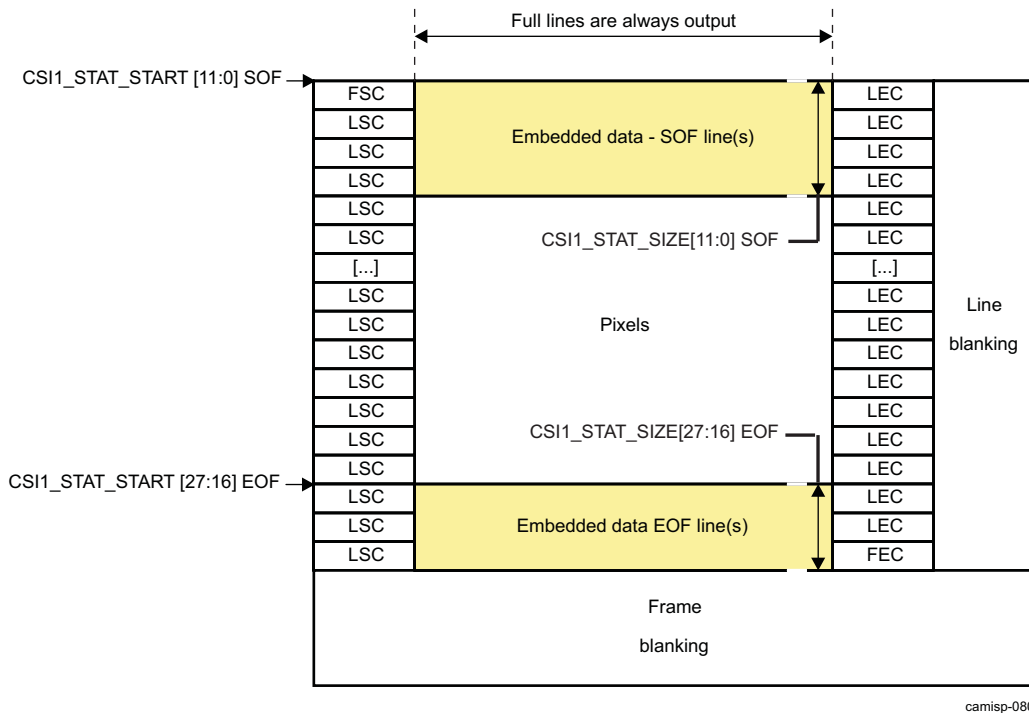

The SOF and EOF status lines always cover full lines. No register settings enable the setting of width.

The CSI1\_STAT\_START register enables the setting of the vertical start position of the SOF and EOF status lines. Because the SOF status line comes first in the CSI1 frame, CSI1\_STAT\_START [11:0] SOF = 0x0.

The CSI1\_STAT\_SIZE register enables the setting of the numbers of SOF and EOF status lines. If CSI1\_STAT\_SIZE [11:0] SOF = 0x0 and CSI1\_STAT\_SIZE [27:16] EOF = 0x0, no status data are output.

The SOF and EOF status lines and the pixel data must not overlap, but can be consecutive. [Figure 12-98](#) shows the SOF and EOF region settings.

**Figure 12-98. SOF and EOF Region Settings**

The 32-bit destination address of the SOF status lines is set by the CSI1\_SOF\_ADDR register.

**NOTE:** The destination address must be aligned on a 32-byte boundary; the address 5 LSBs are ignored. The SOF lines are packed together at the destination address.

The 32-bit destination addresses of the EOF status lines are set by the CSI1\_EOF\_ADDR register.

**NOTE:** The destination address must be aligned on a 32-byte boundary; the address 5 LSBs are ignored. The EOF lines are packed together at the destination address.

**NOTE:** The CSI1 receiver does not modify the data in the SOF and EOF status lines. The data are received and written with no modifications.

### 12.5.2.13 Pixel Data Region

Pixel data can be output to memory or to the video-preprocessing hardware.

The pixel data region covers full lines. The CSI1\_DAT\_SIZE register sets the horizontal size of the pixel region. The vertical size is expressed in lines.

The CSI1\_DAT\_START register enables the setting of the vertical start position of the pixel data. The vertical start position is expressed in lines.

Figure 12-99 shows the pixel region settings.

**Figure 12-99. Pixel Data Region Settings**

camisp-081

The 32-bit destination addresses of the pixel data are set by the `CSI1_DAT_PING_ADDR` and `CSI1_DAT_PONG_ADDR` registers.

**NOTE:** The destination address must be aligned on a 32-byte boundary; the address 5 LSBs are ignored. The pixel data lines are packed together at the destination address.

It is possible to perform double-buffering (ping-ponging) at the destination by setting different addresses in the `CSI1_DAT_PING_ADDR` and `CSI1_DAT_PONG_ADDR` registers. It is possible to disable double-buffering by setting up the same address in both registers. The `CSI1_CTRL1 [17] PING_PONG` status bit must be used by the software to determine which address contains the latest frame.

A destination pitch controls the address jump between the address of the first pixel of the previous line and the address of the first pixel of the current line. The destination pitch is set in bytes with the `CSI1_DAT_OFST` register. It applies for `CSI1_DAT_PING_ADDR` and `CSI1_DAT_PONG_ADDR`.

**NOTE:** The destination pitch must be a multiple of 32 bytes; the address 5 LSBs are ignored.

The use of `CSI1_DAT_OFST` is limited to the following destination data formats:

- YUV422 little endian
- YUV422 big endian
- RGB444 + EXP16
- RGB565

- RGB888 + EXP32

For all other data formats, the CSI1\_CTRL\_DAT\_OFST register is ignored (equivalent to CSI1\_DAT\_OFST = 0x0).

The destination data format is set with the CSI1\_CTRL1 [7:3] FORMAT bit field.

For the PING frame:

- @Line0 = CSI1\_DAT\_PING\_ADDR
- @Line1 = @Line0 + CSI1\_DAT\_OFST
- @Line2 = @Line1 + CSI1\_DAT\_OFST

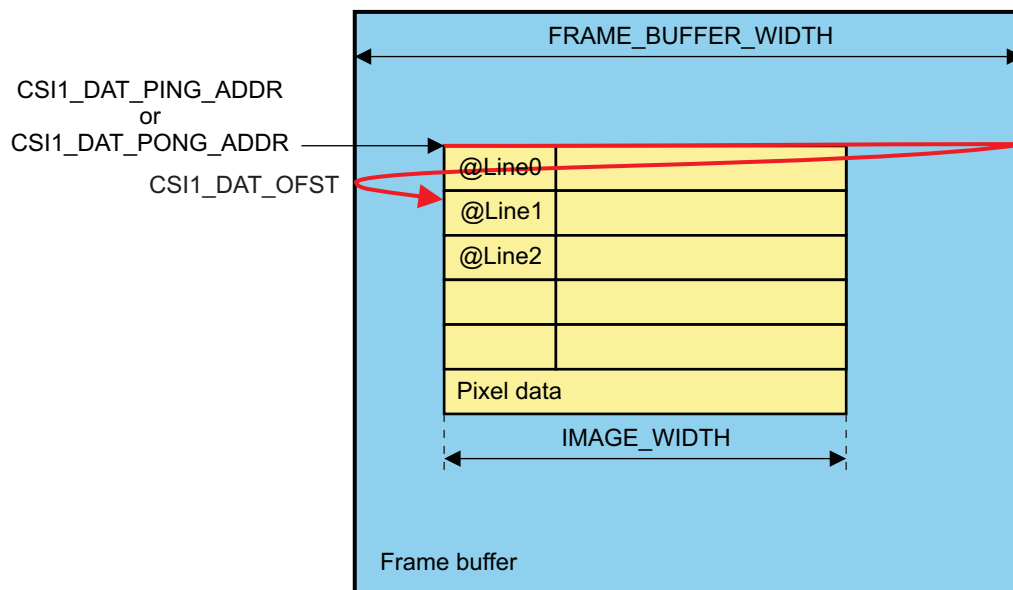

For the PONG frame:

- @Line0 = CSI1\_DAT\_PONG\_ADDR
- @Line1 = @Line0 + CSI1\_DAT\_OFST
- @Line2 = @Line1 + CSI1\_DAT\_OFST

When CSI1\_DAT\_OFST = 0x0, the lines are written contiguously in memory. The destination pitch enables 2D transfers; it is required to write the pixel data directly in the frame buffer, for instance.

In such cases, CSI1\_DAT\_OFST = FRAME\_BUFFER\_WIDTH. Figure 12-100 shows the pixel data settings.

**Figure 12-100. Pixel Data Destination Settings**

camisp-082

### 12.5.2.14 Memory Read Channel

#### 12.5.2.14.1 Write Data From Sensor to Memory

Data can be captured from the sensor using any logical channel. To keep the native data format, the channel format must be set to YUV422 little-endian format.

### 12.5.3 Programming the CSI2 Receiver

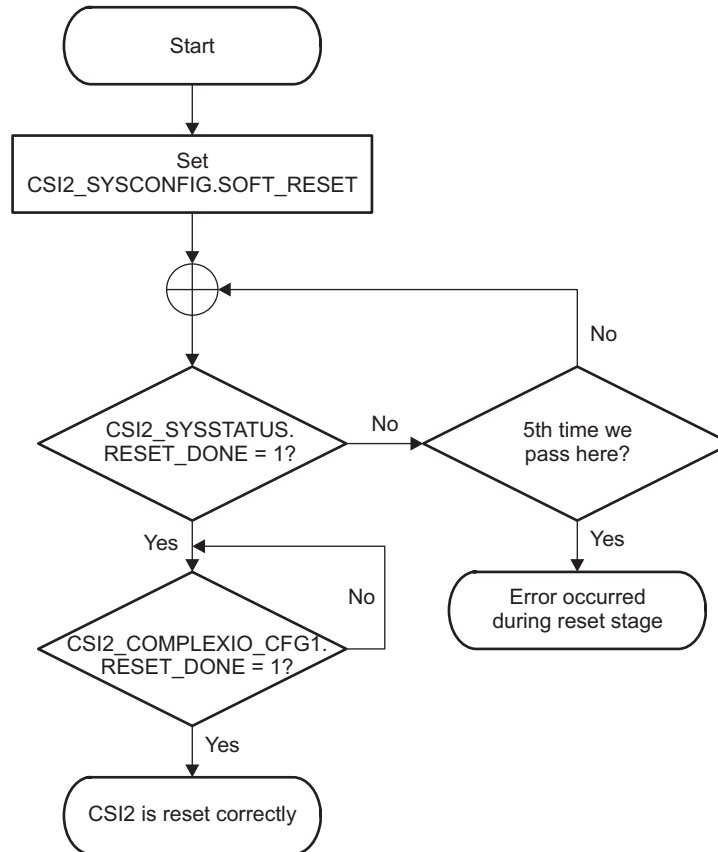

#### 12.5.3.1 Enable CSI2 Interface

The CSI2 interface is clocked by CSI2\_96\_FCLK, which is enabled by setting the CM\_FCLKEN\_CAM[1] EN\_CSI2 bit register to 1.

### 12.5.3.2 Reset Management

The CSI2 receiver accepts a general software reset, propagated throughout the hierarchy. This reset can be done to initialize the CSI2 receiver and the complex I/O and has the same effect as a hardware reset. Figure 12-101 shows how to reset the CSI2 globally.

**Figure 12-101. CSI2 Receiver Global Reset Flow Chart**

camisp-252

Note: CSI2\_COMPLEXIO\_CFG.RESET\_DONE is set to 1 only after the CSI2 receiver, CSI2 complex I/O, and external camera sensor are initialized.

**NOTE:** Before setting the software reset bit to 1 in the CSI2\_SYSCONFIG register, the user must have access to a CSI2 receiver register.

### 12.5.3.3 Enable Video/Picture Acquisition

To start a video/picture acquisition, perform the following steps:

1. Reset the CSI2 receiver module (see Section 12.5.3.2, *Reset Management*).
2. Configure the module power management: Set the CSI2\_SYSCONFIG[13:12] MSTANDBY\_MODE bit field to 0x2 so the module tries to enter smart-standby mode during the vertical blanking period. The CSI2\_SYSCONFIG[0] AUTO\_IDLE bit field keeps its reset value; by default, an automatic port clock gating strategy is applied based on port interface activity
3. Configure the interrupt generation as required using the CSI2\_IRQSTATUS and CSI2\_IRQENABLE registers. To enable context and/or complex I/O event reporting, enable the corresponding bit field in the CSI2\_IRQENABLE register. If the enable bit is at 0, logging is still effective if an event occurs but is not reported to a higher level.
4. Configure the complex I/O interrupt generation as required using the CSI2\_COMPLEXIO1\_IRQSTATUS and CSI2\_COMPLEXIO1\_IRQENABLE registers. If the enable bit

is at 0, logging is still effective if an event occurs but is not reported to a higher level.

5. Initialize the PHY (see [Section 12.5.1.1](#), *Camera ISP Complex I/O Initialization for Work With CSI2 Receiver*).
6. Set the `CSI2_CTRL[2]` `ECC_EN` bit to 1 to activate ECC correction and error detection on short packets and packet headers. The ECC check corrects the packet if there is one error and generates an error if there is more than one error (unrecoverable error).
7. Start the CSI2 receiver by setting the `CSI2_CTRL[0]` `IF_EN` bit to 1.
8. Configure the different contexts to be used (up to eight):
  - (a) Link the context to a virtual channel and a data type (see [Section 12.5.3.7](#), *Linking a Context to a Virtual Channel and a Data Type*).
  - (b) Set the `CSI2_CTX_CTRL1[26:23]` `FEC_NUMBER` bit field to 0x1 for a progressive video and to 0x2 for an interlaced video. For more information, see [Section 12.4.3.7](#), *DMA Engine*.
  - (c) Keep the `CSI2_CTX_CTRL1[15:8]` `COUNT` bit field and the `CSI2_CTX_CTRL1[4]` `COUNT_UNLOCK` bit at their reset values (0x0 and 0, respectively) to capture an infinite number of frames (until the interface or the context is disabled).
  - (d) Set the `CSI2_CTX_CTRL1[5]` `CS_EN` bit to enable the CRC checksum on long packet payload. This allows detection of errors, but cannot correct errors like the ECC for header and short packet. On error detection, an event is triggered (the `CSI2_CTX_IRQSTATUS[5]` `CS_IRQ` bit).
  - (e) Configure the DMA engine for the current channel:
    - Configure the `CSI2_CTX_DAT_PING_ADDR[31:5]` `ADDR` bit field to set the ping frame address in memory.
    - Configure the `CSI2_CTX_DAT_PONG_ADDR[31:5]` `ADDR` bit field to set the pong frame address in memory. If not using a double-buffer mechanism, the ping and pong addresses must be equal so that all frames are stored at the same memory address).
    - Set the `CSI2_CTX_DAT_OFST[15:5]` `OFST` bit field to 0x0, so consecutive lines are stored consecutively in memory (image width and frame-buffer width are equal).

---

**NOTE:** Addresses given for PING and PONG frames are virtual addresses. Address translations are made on the camera MMU and on the Circular Buffer. For more information about the camera MMU module, see [Chapter 8](#), *Memory Management Units*.

---
  - (f) Keep the `CSI2_CTX_CTRL3[29:16]` `ALPHA` bit field at its reset value (0x0) for RGB padding.
9. Enable the contexts to be used by setting the `CSI2_CTX_CTRL1[0]` `CTX_EN` bit to 1.

### 12.5.3.4 Disable Video/Picture Acquisition

There are two ways to end picture acquisition:

- Disable the corresponding context by writing 0 to the `CSI2_CTX_CTRL1[0]` `CTX_EN` bit. This stops the acquisition for the current context. Other enabled contexts are still capturing frames and writing them in memory.
- Disable the CSI2 receiver interface by writing 0 to the `CSI2_CTRL[0]` `IF_EN` bit. This can have an immediate effect if the `CSI2_CTRL[3]` `FRAME` bit is 0, or it can be effective after all the enabled contexts receive the FEC if the `CSI2_CTRL[3]` `FRAME` bit is 1.

### 12.5.3.5 Capture a Finite Number of Frames

The CSI2 receiver module can be configured to capture a finite number of frames. To configure the CSI2 receiver in this mode, perform the following steps:

1. Write 1 to the `CSI2_CTX_CTRL1[4]` `COUNT_UNLOCK` bit to enable a write to the `COUNT` bit field.
2. Set the bit field to the number of frames the CSI2 receiver must capture. Valid values are 0 to 255; 0 is infinite capture and 1 to 255 defines the number of frames to capture.
3. Write 0 to the `CSI2_CTX_CTRL1[4]` `COUNT_UNLOCK` bit to disable a write to the `COUNT` bit field.

During frame capture, the COUNT bit field is decremented by 1 at each frame capture. The software reads the COUNT bit field to know how many frames still must be captured.

The COUNT bit can be updated during capture if the COUNT\_UNLOCK is set to 1.

### 12.5.3.6 Configure a Periodic Event During Frame Acquisition

The CSI2 receiver can generate a periodic event. This line number is defined in the [CSI2\\_CT<sub>x</sub>\\_CTRL3\[15:0\]](#) LINE\_NUMBER bit field. The event can be generated once or multiple times per frame, depending on the [CSI2\\_CT<sub>x</sub>\\_CTRL1\[1\]](#) LINE\_MODULO bit value:

- If the LINE\_MODULO bit = 0, the event is generated when the line number corresponding to the LINE\_NUMBER bit field is received.
- If the LINE\_MODULO bit = 1, the event is generated when the line number received corresponds to a multiple of the LINE\_NUMBER value (LINE\_NUMBER is used as a modulo).

### 12.5.3.7 Linking a Context to a Virtual Channel and a Data Type

The CSI2 receiver supports eight contexts and the CSI2 protocol defines four virtual channels. Therefore, a CSI2 receiver context can be associated with a virtual channel and a data type. Virtual channels are defined by a 2-bit field. Valid data types for the CSI2 receiver with their associated values are described in [Table 12-49](#).

**Table 12-49. CSI2 Receiver-Supported Data Types**

Value	Data Type
0x0	Others
0x12	Embedded 8-bit nonimage data
0x18	YUV420 8-bit
0x19	YUV420 10-bit
0x1A	YUV420 8-bit legacy
0x1C	YUV420 8-bit + CSPS
0x1D	YUV420 10-bit + CSPS
0x1E	YUV422 8-bit
0x1F	YUV422 10-bit
0x22	RGB565
0x24	RGB888
0x28	RAW6
0x29	RWA7
0x2A	RAW8
0x2B	RAW10
0x2C	RAW12
0x2D	RAW14
0x33	RGB666 + EXP32_24
0x40	USER_DEFINED_8_BIT_DATA_TYPE_1
0x41	USER_DEFINED_8_BIT_DATA_TYPE_2
0x42	USER_DEFINED_8_BIT_DATA_TYPE_3
0x43	USER_DEFINED_8_BIT_DATA_TYPE_4
0x44	USER_DEFINED_8_BIT_DATA_TYPE_5
0x45	USER_DEFINED_8_BIT_DATA_TYPE_6
0x46	USER_DEFINED_8_BIT_DATA_TYPE_7
0x47	USER_DEFINED_8_BIT_DATA_TYPE_8
0x68	RAW6 + EXP8
0x69	RAW7 + EXP8
0x80	USER_DEFINED_8_BIT_DATA_TYPE_1 + EXP8

**Table 12-49. CSI2 Receiver-Supported Data Types (continued)**

Value	Data Type
0x81	USER_DEFINED_8_BIT_DATA_TYPE_2 + EXP8
0x82	USER_DEFINED_8_BIT_DATA_TYPE_3 + EXP8
0x83	USER_DEFINED_8_BIT_DATA_TYPE_4 + EXP8
0x84	USER_DEFINED_8_BIT_DATA_TYPE_5 + EXP8
0x85	USER_DEFINED_8_BIT_DATA_TYPE_6 + EXP8
0x86	USER_DEFINED_8_BIT_DATA_TYPE_7 + EXP8
0x87	USER_DEFINED_8_BIT_DATA_TYPE_8 + EXP8
0x9E	YUV422 8bit + VP
0xA0	RGB444 + EXP16
0xA1	RGB555 + EXP16
0xAB	RAW10 + EXP16
0xAC	RAW12 + EXP16
0xAD	RAW14 + EXP16
0xE3	RGB666 + EXP32

0x2AA	RAW8 + DPCM10 + EXP16
0x2C0	USER_DEFINED_8_BIT_DATA_TYPE_1 + DPCM10 + EXP16
0x2C1	USER_DEFINED_8_BIT_DATA_TYPE_2 + DPCM10 + EXP16
0x2C2	USER_DEFINED_8_BIT_DATA_TYPE_3 + DPCM10 + EXP16
0x2C3	USER_DEFINED_8_BIT_DATA_TYPE_4 + DPCM10 + EXP16
0x2C4	USER_DEFINED_8_BIT_DATA_TYPE_5 + DPCM10 + EXP16
0x2C5	USER_DEFINED_8_BIT_DATA_TYPE_6 + DPCM10 + EXP16
0x2C6	USER_DEFINED_8_BIT_DATA_TYPE_7 + DPCM10 + EXP16
0x2C7	USER_DEFINED_8_BIT_DATA_TYPE_8 + DPCM10 + EXP16
0x329	RAW7 + DPCM10 + VP
0x32A	RAW8 + DPCM10 + VP
0x340	USER_DEFINED_8_BIT_DATA_TYPE_1 + DPCM10 + VP
0x341	USER_DEFINED_8_BIT_DATA_TYPE_2 + DPCM10 + VP
0x342	USER_DEFINED_8_BIT_DATA_TYPE_3 + DPCM10 + VP
0x343	USER_DEFINED_8_BIT_DATA_TYPE_4 + DPCM10 + VP
0x344	USER_DEFINED_8_BIT_DATA_TYPE_5 + DPCM10 + VP
0x345	USER_DEFINED_8_BIT_DATA_TYPE_6 + DPCM10 + VP
0x346	USER_DEFINED_8_BIT_DATA_TYPE_7 + DPCM10 + VP
0x347	USER_DEFINED_8_BIT_DATA_TYPE_8 + DPCM10 + VP

For each context, a [CSI2\\_CTX\\_CTRL2](#) register defines with which channel and data type the context is associated:

- The VIRTUAL\_ID field defines the associated virtual ID transported by the CSI2 protocol from the camera sensor.
- The FORMAT field defines the associated data type. The data type is a combination of the data type transported by the CSI2 protocol and the type of storage in memory. A given data type (RGB888) can

be stored in memory in different ways (RGB888 or RGB888 + EXP32). Therefore, the FORMAT field also defines the way DMA stores data in memory.

For example, for the current context to capture a frame from virtual channel 2 and data type RAW12 with data expansion (RAW12 + EXP16), write the value 0x10AC (0x2 11 + 0xAC) in the 16 LSBs of the [CSI2\\_CTLx\\_CTRL2](#) register.

### 12.5.3.8 Progressive and Interleaved Frame Configuration

The CSI2 receiver can treat both progressive and interlaced frames. There is no progressive or interleaved mode, but the [CSI2\\_CTLx\\_CTRL1\[23:16\]](#) FEC\_NUMBER field controls the number of FECs before swapping to the other (ping or pong) buffer. Therefore, two modes are possible:

- FEC\_NUMBER = 1: This is equivalent to progressive mode. After a FEC on the context, the current buffer is switched (ping to pong or pong to ping). The image in the memory buffer consists of one transmitted frame.
- FEC\_NUMBER != 1: The current buffer is switched (ping to pong or pong to ping) after the FEC\_NUMBER FEC is received for the context. The image in the memory buffer consists of the FEC\_NUMBER transmitted frame.

For more information about how data is stored in memory through the DMA, see [Section 12.4.3.7, DMA Engine](#).

---

**NOTE:** If FEC\_NUMBER != 1, the camera sensor must send the line number information with the current line. Otherwise, the CSI2 receiver cannot calculate each line address.

---

## 12.5.4 Programming the Timing CTRL Module

---

**NOTE:** All the following settings must be done before enabling the timing control module.

---

### 12.5.4.1 Timing Generator

The cam\_xclka clock frequency is set through the [TCTRL\\_CTRL\[4:0\]](#) DIVA bit field. The cam\_xclkb clock frequency is set through the [TCTRL\\_CTRL\[9:5\]](#) DIVB bit field. One can change the divisor values at any time.

For divisor values 0, 1, and 31, the divider is not enabled. For all other values:

- cam\_xclka = cam\_mclk/[TCTRL\\_CTRL\[4:0\]](#) DIVA
- cam\_xclkb = cam\_mclk/[TCTRL\\_CTRL\[9:5\]](#) DIVB

### 12.5.4.2 Camera-Control Signal Generator

Enabling of the SHUTTER, PRESTROBE or STROBE signals generation and activates the counters:

- [TCTRL\\_CTRL\[21\]](#) SHUTEN = 1
- [TCTRL\\_CTRL\[22\]](#) PSTRBEN = 1
- [TCTRL\\_CTRL\[23\]](#) STRBEN = 1

Two configurations apply:

- The control signals are based on the vertical synchronization information coming from the camera module or from the externally generated cam\_global\_reset signal.
- The control signals are based on the internally generated cam\_global\_reset.

#### 12.5.4.2.1 Vertical Synchro-Based Control-Signal Generation or Externally-Generated cam\_global\_reset

Before enabling the control-signal generation, the following registers must be set:

- Select the input that triggers the control signals. The trigger signal can come from the PARALLEL, CS1a, or CS1b interface, or the externally-generated cam\_global\_reset signal.

- [TCTRL\\_CTRL\[28:27\]](#) INSEL
- The signal must be set to INPUT:
  - [TCTRL\\_CTRL\[31\]](#) GRESETDIR = 0x0
  - Writes to [TCTRL\\_CTRL\[29\]](#) GRESETEN bit do not trigger the PRESTROBE, STROBE, and SHUTTER signals, and do not generate the cam\_global\_reset signal.
- The following bits are cleared automatically to 0 after the signal assertion:
  - [TCTRL\\_CTRL\[21\]](#) SHUTEN
  - [TCTRL\\_CTRL\[22\]](#) PSTRBEN
  - [TCTRL\\_CTRL\[23\]](#) STRBEN
- The following bits set the polarity of the SHUTTER, STROBE/PRESTROBE, and cam\_global\_reset signals. The signals can be active high or active low:
  - [TCTRL\\_CTRL\[24\]](#) SHUTPOL
  - [TCTRL\\_CTRL\[26\]](#) STRBPSTRBPOL
  - [TCTRL\\_CTRL\[30\]](#) GRESETPOL
- The following bit sets the clock divisor value, which generates the CNTCLK clock:
  - [TCTRL\\_CTRL\[18:10\]](#) DIVC

The clock is set by  $CNTCLK = cam\_mclk / TCTRL\_CTRL[18:10] \text{ DIVC}$ . The possible values are 0 to 511. Setting DIVC = 0 disables the CNTCLK clock generation.
- The frame counters are set with (possible values are 0 to 63 frames):
  - [TCTRL\\_FRAME\[5:0\]](#) SHUT
  - [TCTRL\\_FRAME\[11:6\]](#) PSTRB
  - [TCTRL\\_FRAME\[17:12\]](#) STRB

---

**NOTE:** If the value is zero, the Timing Control module does not delay any frame in input.

---

- The delay counters are set with:
  - [TCTRL\\_SHUT\\_DELAY](#)
  - [TCTRL\\_PSTRB\\_DELAY](#)
  - [TCTRL\\_STRB\\_DELAY](#)

The possible values are 0 to  $2^{25} - 1$  cycles. The cycles are at the CNTCLK clock frequency. The maximum signal duration is  $(2^{25} - 1) \times 2.366 \text{ s} = 79 \text{ s}$  ([TCTRL\\_CTRL\[18:10\]](#) DIVC = 511).
- The signal durations are set with:
  - [TCTRL\\_SHUT\\_LENGTH](#)
  - [TCTRL\\_PSTRB\\_LENGTH](#)
  - [TCTRL\\_STRB\\_LENGTH](#)

The possible values are 0 to  $2^{24} - 1$  cycles. The cycles are at the CNTCLK clock frequency. The maximum signal duration is  $(2^{24} - 1) \times 2.366 \text{ s} = 39.69 \text{ s}$  ([TCTRL\\_CTRL\[18:10\]](#) DIVC = 511).

#### 12.5.4.2.2 Internally-Generated cam\_global\_reset-Based Control-Signal Generation

Before enabling the cam\_global\_reset control-signal generation by writing [TCTRL\\_CTRL\[29\]](#) GRESETEN = 1, the following registers must be set:

---

**NOTE:** Setting [TCTRL\\_CTRL\[21\]](#) SHUTEN, [TCTRL\\_CTRL\[22\]](#) PSTRBEN, [TCTRL\\_CTRL\[23\]](#) STRBEN, and [TCTRL\\_CTRL\[29\]](#) GRESETEN to 1 simultaneously leads to unpredictable behavior. The [TCTRL\\_CTRL\[21\]](#) SHUTEN, [TCTRL\\_CTRL\[22\]](#) PSTRBEN, [TCTRL\\_CTRL\[23\]](#) STRBEN must be set before [TCTRL\\_CTRL\[29\]](#) GRESETEN is enabled.

---

- The signal must be set to OUTPUT:
  - [TCTRL\\_CTRL\[31\]](#) GRESETDIR = 0x1

- Vertical synchronization events do not trigger the PRESTROBE, STROBE, and SHUTTER signals.
- The following bits are cleared automatically to 0 after the signal assertion:
  - [TCTRL\\_CTRL\[21\]](#) SHUTEN
  - [TCTRL\\_CTRL\[22\]](#) PSTRBEN
  - [TCTRL\\_CTRL\[23\]](#) STRBEN
  - [TCTRL\\_CTRL\[29\]](#) GRESETEN
- The following bits set the polarity of the SHUTTER, STROBE/PRESTROBE, and cam\_global\_reset signals. The signals can be active high or active low:
  - [TCTRL\\_CTRL\[24\]](#) SHUTPOL
  - [TCTRL\\_CTRL\[26\]](#) STRBPSTRBPOL
  - [TCTRL\\_CTRL\[30\]](#) GRESETPOL
- The following bit sets the clock divisor value, which generates the CNTCLK clock:
  - [TCTRL\\_CTRL\[18:10\]](#) DIVC
 

The clock is set by  $CNTCLK = cam\_mclk / TCTRL\_CTRL[18:10] \text{ DIVC}$ . The possible values are 0 to 511. Setting  $DIVC = 0$  disables the CNTCLK clock generation.
- The frame counters bit fields are ignored:
  - [TCTRL\\_FRAME\[5:0\]](#) SHUT
  - [TCTRL\\_FRAME\[11:6\]](#) PSTRB
  - [TCTRL\\_FRAME\[17:12\]](#) STRB
- The delay counters are set with:
  - [TCTRL\\_SHUT\\_DELAY](#)
  - [TCTRL\\_PSTRB\\_DELAY](#)
  - [TCTRL\\_STRB\\_DELAY](#)

The possible values are 0 to 225 -1 cycle. The cycles are at the CNTCLK clock frequency. The maximum signal duration is  $(2^{25} - 1) \times 2.366 \text{ s} = 79 \text{ s}$  ([TCTRL\\_CTRL\[18:10\]](#)  $DIVC = 511$ ).
- The signal durations are set with:
  - [TCTRL\\_SHUT\\_LENGTH](#)
  - [TCTRL\\_PSTRB\\_LENGTH](#)
  - [TCTRL\\_STRB\\_LENGTH](#)

The possible values are 0 to 224 -1 cycle. The cycles are at the CNTCLK clock frequency. The maximum signal duration is  $(2^{24} - 1) \times 2.366 \text{ s} = 39.69 \text{ s}$  ([TCTRL\\_CTRL\[18:11\]](#)  $DIVC = 511$ ).
- The cam\_global\_reset assertion time is set by [TCTRL\\_GRESET\\_LENGTH](#). The possible values are 0 to 224 -1 cycle. The cycles are at the CNTCLK clock frequency. The maximum signal duration is  $(2^{24} - 1) \times 2.366 \text{ s} = 39.69 \text{ s}$  ([TCTRL\\_CTRL\[18:11\]](#)  $DIVC = 511$ ).

### 12.5.4.2.3 STROBE and PRESTROBE Signal Generation for Red-Eye Removal

The STROBE and PRESTROBE signal generation enables a strobe flash for red eye removal. The process is shown in [Figure 12-102](#). The dotted line corresponds to known timings from which the delay counters start decreasing: cam\_global\_reset event.

Figure 12-102. cam\_strobe Signal-Generation for Red-Eye Removal

- t1: Set by the [TCTRL\\_PSTRB\\_DELAY](#) register
- t2: set by the [TCTRL\\_PSTRB\\_LENGTH](#) register
- t5: set by the [TCTRL\\_PSTRB\\_REPLAY\[24:0\]](#) DELAY bit field. The number of times the pulse is repeated is controlled by the [TCTRL\\_PSTRB\\_REPLAY \[31:25\]](#) COUNTER register. In the former example, [TCTRL\\_PSTRB\\_REPLAY \[31:25\]](#) COUNTER = 2.
  - The possible delay values are 0 to  $2^{25} - 1$  cycle. The cycles are at the CNTCLK clock frequency. The maximum signal duration is  $(2^{25} - 1) \times 2.366 \text{ s} = 79 \text{ s}$  ([TCTRL\\_CTRL\[18:11\]](#) DIVC = 511).
  - The possible count values are 0 to 127 additional pulses.
- t3: Set by the [TCTRL\\_STRB\\_DELAY](#) register
- t4: Set by the [TCTRL\\_STRB\\_LENGTH](#) register

camisp-083

## 12.5.5 Programming the CCDC

This section discusses issues related to the software control of the CCDC. It lists which registers are required to be programmed in different modes, and describes how to enable and disable the CCDC, how to check the status of the CCDC, the different register access types, and programming constraints.

### 12.5.5.1 CCDC Hardware Setup/Initialization

This section discusses the configuration of the CCDC required before image processing can begin.

#### 12.5.5.1.1 Reset Behavior

On hardware reset of the camera ISP, all registers in the CCDC are reset to their reset values.

#### 12.5.5.1.2 Register Setup

Before enabling the CCDC, the hardware must be correctly configured through register writes. [Table 12-50](#) identifies the register parameters that must be programmed before enabling the CCDC.

**Table 12-50. CCDC Required Configuration Parameters**

Function	Configuration Required
External pin signal configuration	CCDC_SYN_MODE[0] VDHDOUT CCDC_SYN_MODE[16] VDHDEN CCDC_SYN_MODE[2] VDPOL CCDC_SYN_MODE[3] HDPOL CCDC_SYN_MODE[7] FLDMODE CCDC_SYN_MODE[1] FLDOU CCDC_SYN_MODE[4] FLDPOL CCDC_SYN_MODE [5] EXWEN CCDC_SYN_MODE[6] DATAPOL CCDC_CFG[15] VDLC = 1 ISP_CTRL[3:2] PAR_BRIDGE ISP_CTRL[7:6] SHIFT ISP_CTRL[4] PAR_CLK_POL
Input mode	[0] R656ON CCDC_SYN_MODE[13 :12] INPMOD
Color pattern	CCDC_COLPTN
Black compensation	CCDC_BLKCMP
Faulty-pixel correction	CCDC_FPC[15] FPCEN
Data-path configuration	CCDC_FMTCFG[15] VPEN CCDC_SYN_MODE[18] VP2SDR CCDC_SYN_MODE[17] WEN CCDC_SYN_MODE[19] SDR2RSZ
Lens-shading compensation	CCDC_LSC_CONFIG[0] ENABLE

Table 12-51 identifies additional configuration requirements depending on whether the corresponding condition is met.

Table 12-51 can be read as: if (**Condition** is TRUE), then **Configuration Required** parameters must be programmed.

**Table 12-51. CCDC Conditional Configuration Parameters**

Function	Condition	Configuration Required
VD/HD set as outputs	CCDC_SYN_MODE[0] VDHDOUT = 0x1	CCDC_HD_VD_WID CCDC_PIX_LINES
Interlaced fields	CCDC_SYN_MODE[7] FLDMODE = 0x1	CCDC_CFG[7:6] FIDMD
External WEN	CCDC_SYN_MODE[5] EXWEN = 0x1	CCDC_CFG[8] WENLOG

### 12.5.5.1.3 Pixel Selection (Framing) Register Dependencies

There are three locations in the data flow where the valid frame data can be defined:

- Data formatter input pixel selection
- Video port output pixel selection
- Output formatter pixel selection

Care must be taken to ensure that the frame definitions correspond to the output of the upstream frame definitions. When the video port is enabled, [CCDC\\_VP\\_OUT](#)[30:17] VERT\_NUM must be less than [CCDC\\_FMT\\_VERT](#)[12:0] FMTLNV.

Two data paths through the CCDC affect the programming of the pixel-selection registers, depending on the value of the [CCDC\\_SYN\\_MODE](#)[18] VP2SDR bit:

- VP2SDR = 0: The input data bypasses the data formatter/video port. In this case, only the memory output frame parameters apply. This data path is represented by the white arrow in [Figure 12-103](#).
- VP2SDR = 1: The input data passes through the data formatter/video port. In this case, both data formatter frame definitions apply to the video-port output, and all three frame definitions apply to the memory output. This data path is represented by the green shaded arrow in [Figure 12-103](#).

Figure 12-103. Dependencies Among Framing Settings in Data Flow

camisp-084

### 12.5.5.2 Enable/Disable Hardware

All required registers mentioned in the previous section must be programmed before setting the [CCDC\\_PCR\[0\]](#) ENABLE bit.

The CCDC always operates in continuous mode. In other words, after enabling the CCDC, it processes sequential frames until the ENABLE bit is cleared by software. When this happens, the frame being processed completes before the CCDC is disabled.

When the CCDC is in master mode (HS/VS signals set to outputs), fetching and processing of the frame begin immediately on setting the [CCDC\\_PCR\[0\]](#) ENABLE bit.

When the CCDC is in slave mode (HS/VS signals set to inputs), processing of the frame depends on the input timing of the external sensor/decoder. To ensure that data from the external device is not missed, the CCDC must be enabled before data transmission from the external device. In this way, the CCDC waits for data from the external device.

On setting the [CCDC\\_FPC\[15\]](#) FPCEN bit, the CCDC begins to fetch and buffer the faulty-pixel table from memory. If faulty-pixel correction is used, the [CCDC\\_FPC\[15\]](#) FPCEN bit must be set before the [CCDC\\_PCR\[0\]](#) ENABLE bit, but after the faulty-pixel table is placed in memory and the [CCDC\\_FPC\[14:0\]](#) FPNUM and [CCDC\\_FPC\\_ADDR](#) registers are set.

### 12.5.5.3 Events and Status Checking

The CCDC can generate three different interrupts: [CCDC\\_VD0\\_IRQ](#), [CCDC\\_VD1\\_IRQ](#), and [CCDC\\_VD2\\_IRQ](#).

The [CCDC\\_SYN\\_MODE\[16\]](#) VDHDEN bit must be enabled to receive any of the CCDC [CCDC\\_VDx\\_IRQ](#) interrupts.

#### 12.5.5.3.1 Interrupts

The CCDC module has three programmable events: [CCDC\\_VD0\\_IRQ](#), [CCDC\\_VD1\\_IRQ](#), and [CCDC\\_VD2\\_IRQ](#), and one error event [CCDC\\_ERR\\_IRQ](#). Event generation is described in [Section 12.5.5.3.2, \*CCDC\\_VD0\\_IRQ and CCDC\\_VD1\\_IRQ Interrupts\*](#), and [Section 12.5.5.3.3, \*CCDC\\_VD2\\_IRQ Interrupt\*](#).

CCDC module events can be mapped to the ARM or the DSP:

- The [CCDC\\_VD0\\_IRQ](#), [CCDC\\_VD1\\_IRQ](#), [CCDC\\_VD2\\_IRQ](#), and [CCDC\\_ERR\\_IRQ](#) bits in the [ISP\\_IRQ0ENABLE](#) register control whether the CCDC module events trigger an interrupt to the ARM. The [ISP\\_IRQ0STATUS](#) register indicates which event(s) triggered the interrupt. An event is cleared by writing a 1 in its corresponding bit in the [ISP\\_IRQ0STATUS](#) register. To clear the [CCDC\\_ERR\\_IRQ](#) interrupt, clear the [CCDC\\_FPC\[16\]](#) FPERR bit before clearing the [ISP\\_IRQ0STATUS\[11\]](#) [CCDC\\_ERR\\_IRQ](#) bit.
- The [CCDC\\_VD0\\_IRQ](#), [CCDC\\_VD1\\_IRQ](#), [CCDC\\_VD2\\_IRQ](#), and [CCDC\\_ERR\\_IRQ](#) bits in the [ISP\\_IRQ1ENABLE](#) register control whether the CCDC module events trigger an interrupt to the DSP. The [ISP\\_IRQ1STATUS](#) register indicates which event(s) triggered the interrupt. An event is cleared by writing a 1 in its corresponding bit in the [ISP\\_IRQ1STATUS](#) register. To clear the [CCDC\\_ERR\\_IRQ](#) interrupt, clear the [CCDC\\_FPC\[16\]](#) FPERR bit before clearing the [ISP\\_IRQ1STATUS\[11\]](#) [CCDC\\_ERR\\_IRQ](#) bit.

#### 12.5.5.3.2 CCDC\_VD0\_IRQ and CCDC\_VD1\_IRQ Interrupts

As shown in [Figure 12-104](#), the [CCDC\\_VD0\\_IRQ](#) and [CCDC\\_VD1\\_IRQ](#) interrupts occur relative to the VS pulse. The trigger timing is selected by using the [CCDC\\_SYN\\_MODE\[2\]](#) VDPOL setting. [CCDC\\_VD0\\_IRQ](#) and [CCDC\\_VD1\\_IRQ](#) occur after receiving the number of horizontal lines (HS pulse signals) set in the [CCDC\\_VDINT\[30:16\]](#) VDINT0 and [CCDC\\_VDINT\[14:0\]](#) VDINT1 register fields, respectively.

---

**NOTE:** In the case of BT.656 input mode, there is VS at the beginning of each field. Therefore, there are two interrupts for each frame (one for each field).

---

If [CCDC\\_SYN\\_MODE\[2\]](#) VDPOL is 0, the CCDC\_VD0\_IRQ and CCDC\_VD1\_IRQ HS counters begin counting HS pulses from the rising edge of the external VS, as shown in [Figure 12-104](#).

**Figure 12-104. CCDC\_VD0\_IRQ/CCDC\_VD1\_IRQ Interrupt Behavior When VDPOL = 0**

camisp-085

If [CCDC\\_SYN\\_MODE\[2\]](#) VDPOL is 1, the CCDC\_VD0\_IRQ and CCDC\_VD1\_IRQ HS counters begin counting HS pulses from the falling edge of the external VS.

**Figure 12-105. CCDC\_VD0\_IRQ/CCDC\_VD1\_IRQ Interrupt Behavior When VDPOL = 1**

camisp-086

### 12.5.5.3.3 CCDC\_VD2\_IRQ Interrupt

In addition to the CCDC\_VD0\_IRQ and CCDC\_VD1\_IRQ interrupts, the CCDC has an interrupt called CCDC\_VD2\_IRQ. This interrupt always occurs at the falling edge of the WEN signal (through external pin). There are no registers in the CCDC module to configure this interrupt (see [Figure 12-106](#)).

**Figure 12-106. CCDC\_VD2\_IRQ Interrupt Behavior**

camisp-087

### 12.5.5.3.4 Status Checking

The [CCDC\\_PCR](#) [1] BUSY status bit is set when the start of frame occurs (if the [CCDC\\_PCR](#)[0] ENABLE bit is 1 at that time). It is automatically reset to 0 at the end of a frame. The [CCDC\\_PCR](#)[1] BUSY status bit may be polled to determine end-of-frame status.

The [CCDC\\_FPC](#)[16] FPERR status bit is set when faulty-pixel data fetched from memory arrives late. This bit can be reset by writing a 1 to the bit.

### 12.5.5.4 Register Accessibility During Frame Processing

There are three types of register access in the CCDC:

- Shadowed registers: In the CCDC, two register fields are shadowed in different ways. Shadowed registers can be read and written at any time, but the written values take effect (are latched) only at certain times, based on some event. Reads return the most recent write, even though the settings are not used until the specific event occurs. The shadowed registers are:
  - [CCDC\\_PCR](#)[0] ENABLE
    - Written values take effect only at the start of a frame event (rising edge of VD if [CCDC\\_SYN\\_MODE](#)[2] VDPOL is positive, or falling edge of VD if [CCDC\\_SYN\\_MODE](#)[2] VDPOL is negative).
  - [CCDC\\_SDR\\_ADDR](#)

- When [CCDC\\_CFG\[15\]](#) VDLC is set to 0, written values take effect only at the start of a frame event (rising edge of VD if [CCDC\\_SYN\\_MODE\[2\]](#) VDPOL is positive, or falling edge of VD if [CCDC\\_SYN\\_MODE\[2\]](#) VDPOL is negative). When [CCDC\\_CFG\[15\]](#) VDLC is set to 1, written values take effect only at the start of the frame being output to memory (when the input has reached the [CCDC\\_HORZ\\_INFO\[30:16\]](#) SPH pixel of the [CCDC\\_VERT\\_START\[30:16\]](#) SLV0 or [CCDC\\_VERT\\_START\[14:0\]](#) SLV1 line of each field).
- Busy-writable registers: These registers/fields can be read or written even if the module is busy. Changes to the underlying settings occur instantaneously.  
All register fields in the CCDc not formerly listed as shadowed or below as optionally shadowed/busy-writable are busy-writable registers.
- Optionally Shadowed/Busy-Writable registers: All registers/fields listed below can be set as either shadow registers or busy-writable registers:
  - When [CCDC\\_CFG\[15\]](#) VDLC is 0, these registers are shadowed.
  - When [CCDC\\_CFG\[15\]](#) VDLC is 1, these registers are busy-writable.

---

**NOTE:** [CCDC\\_CFG\[15\]](#) VDLC must be set to 1 by software if the CCDc is to be used; therefore, these registers are busy-writable. If [CCDC\\_CFG\[15\]](#) VDLC remains set to 0 (default), indeterminate results may occur for ANY register access in the CCDc, not just those listed in the following.

---

- Optionally shadowed or busy-writable registers
  - [CCDC\\_SYN\\_MODE\[19\]](#) SDR2RSZ
  - [CCDC\\_SYN\\_MODE\[18\]](#) VP2SDR
  - [CCDC\\_SYN\\_MODE\[16\]](#) VDHDEN
  - [CCDC\\_SYN\\_MODE\[17\]](#) WEN
  - [CCDC\\_SYN\\_MODE\[14\]](#) LPF
  - [CCDC\\_HD\\_VD\\_WID](#)
  - [CCDC\\_PIX\\_LINES](#)
  - [CCDC\\_HORZ\\_INFO](#)
  - [CCDC\\_VERT\\_START](#)
  - [CCDC\\_VERT\\_LINES](#)
  - [CCDC\\_CULLING](#)
  - [CCDC\\_HSIZE\\_OFF](#)
  - [CCDC\\_SDOFST](#)
  - [CCDC\\_CLAMP\[31\]](#) CLAMPEN
  - [CCDC\\_FMTCFG\[0\]](#) FMTEN
  - [CCDC\\_LSC\\_CONFIG](#)
  - [CCDC\\_LSC\\_INITIAL](#)
  - [CCDC\\_LSC\\_TABLE\\_BASE](#)
  - [CCDC\\_LSC\\_TABLE\\_OFFSET](#)

### 12.5.5.5 Interframe Operations

Between frames, it may be necessary to enable/disable functions or modify memory pointers. Because the [CCDC\\_PCR](#) register and memory pointer registers are shadowed, these modifications can take place any time before the end of the frame, and the data is latched in for the next frame. The MPU subsystem can perform these changes on receiving an interrupt.

## 12.5.5.6 CCDC Operations

### 12.5.5.6.1 Image-Sensor Configuration

#### 12.5.5.6.1.1 Input-Mode Selection

The CCDC module supports two modes: SYNC mode and ITU-R BT.656 mode. Specific settings correspond to each mode.

- SYNC mode:
  - In this mode, the input data can be either raw data or YCbCr data. Setting `CCDC_SYN_MODE.INPMODE = 0` selects raw data, and `CCDC_SYN_MODE[13:12] INPMODE = 1` or `2` selects YCbCr data on 16 or 8 bits. If `CCDC_SYN_MODE[13:12] INPMODE = 0`, the `cam_d` signal width is selected through `CCDC_SYN_MODE[10:8] DATSIZ`: the possible values are 8, 10, 11, and 12 bits.
  - If `CCDC_SYN_MODE[13:12] INPMODE = 1`, the `cam_d` signal width is 8 bits, but the internal CCDC module data path is configured to 16 bits. It is mandatory to enable the 8- to 16-bit bridge by setting `ISP_CTRL[3:2] PAR_BRIDGE = 2` or `3`. The `ISP_CTRL [3:2] PAR_BRIDGE` bit also controls how the 8-bit data is mapped onto the 16-bit data.
  - The value set in `CCDC_SYN_MODE[10:8] DATSIZ` does not matter. The position of the Y component can be set with the `CCDC_CFG[11] Y8POS` bit.
  - If `CCDC_SYN_MODE[13:12] INPMODE = 2`, the `cam_d` signal width is 8 bits. The value set in `CCDC_SYN_MODE[10:8] DATSIZ` does not matter. The position of the Y component can be set with the `CCDC_CFG[11] Y8POS` bit.
  - The internal timing generator must be enabled with `CCDC_SYN_MODE[16] VDHDEN = 1`.
- ITU mode:
  - In this mode, the data follows the protocol set by the ITU-R BT.656 protocol. To select it, set `CCDC_REC656IF[0] R656ON = 1`. When this mode is selected, the values set in `CCDC_SYN_MODE[13:12] INPMODE` and `CCDC_SYN_MODE[10:8] DATSIZ` do not matter.
  - To select the 8-bit or 10-bit protocol, set the `CCDC_CFG[5] BW656` bit field. Data line `cam_d [7:0]` are used for 8-bit YCbCr and `cam_d[9:0]` are used for 10-bit YCbCr.
  - FVH error correction is enabled by setting `CCDC_REC656IF[1] ECCFVH = 1`.
  - The internal timing generator must be enabled with `CCDC_SYN_MODE[16] VDHDEN = 1`.

#### 12.5.5.6.1.2 Timing Generator and Frame Settings

The polarities of the `cam_hs`, `cam_vs`, and `cam fld` signals are controlled by the `CCDC_SYN_MODE[3] HDPOL`, `CCDC_SYN_MODE[2] VDPOL`, and `CCDC_SYN_MODE[4] FLDPOL` bit fields. The polarities can be positive or negative.

The pixel data is presented on `cam_d` one pixel for every `cam_pclk` rising edge or falling edge. It is controlled with the `ISP_CTRL[4] PAR_CLK_POL` bit.

The `CCDC_SYN_MODE[7] FLDMODE` bit fields set the image-sensor type to progressive or interlaced mode. When the sensor is interlaced, the `CCDC_SYN_MODE[15] FLDSTAT` status bit indicates whether the current frame is odd or even.

The polarity of the `cam_d` signal can also be controlled with the `CCDC_SYN_MODE[6] DATAPOL` bit field. The polarity can be normal mode or ones complement mode.

Furthermore, the directions of the `cam fld` and `cam_hs/cam_vs` signals are controlled by the `CCDC_SYN_MODE[1] FLDOUT` and `CCDC_SYN_MODE[0] VDHDOUT` bits. If `CCDC_SYN_MODE[0] VDHDOUT` is set as an output, the `CCDC_PIX_LINES` register controls the length of the `cam_hs` and `cam_vs` signals.

If `CCDC_SYN_MODE[0] VDHDOUT = 1`:

- The HS sync pulse width is given by `CCDC_HD_VD_WID[27:16] HDW`. The VS sync pulse width is given by `CCDC_HD_VD [11:0] VDW`.
- The HS period is given by `CCDC_PIX_LINES[31:16] PPLN`. The VS period is given by

CCDC\_PIX\_LINES[15:0] HLP RF x 2.

Figure 12-107 shows the HS/VS sync pulse output timings.

Figure 12-107. HS/VS Sync Pulse Output Timings

camisp-117

### 12.5.5.6.1.3 Mosaic Filter Settings

The CCDC module supports image sensors with R, G, and B primary color mosaic filters and Ye, Cy, Mg, and G complementary color mosaic filters. The mosaic filter layout pattern is controlled by the [CCDC\\_COLPTN](#) register. Each bit field in this register controls the color associated to one pixel in a 4x4 region area. The 4x4 area repeats horizontally and vertically.

Figure 12-108 shows configuration examples of the [CCDC\\_COLPTN](#) register. It is assumed that CP0LPC0 is the first pixel output and CP3LPC3 is the last pixel output during frame readout.

**Figure 12-108. Mosaic Filter - CCDC\_COLPTN Bit Field Settings**

camisp-088

### 12.5.5.6.2 Image-Signal Processing

#### 12.5.5.6.2.1 Digital Clamp

Digital clamp is enabled only if optical black clamping is disabled: `CCDC_CLAMP[31] CLAMPEN = 0`. The digital clamp DC value to be subtracted from the raw image data (`CCDC_SYN_MODE[13:12] INPMOD = 0`) or from the luminance (`CCDC_SYN_MODE[13:12] INPMOD = 0` or `CCDC_REC656IF[0] R656ON = 1`) is set with the `CCDC_DCSUB` register. The DC value can range from 0 to 212-1. The reset value is 0.

#### 12.5.5.6.2.2 Optical Black Clamping

Optical black clamping is enabled by setting `CCDC_CLAMP[31] CLAMPEN` to 1. When enabled, an average of black-pixel samples is computed over a window. If the height of the window is  $2N$ , the average value multiplied by a programmable gain factor is subtracted from the raw image data for the following  $2N$  lines. Every  $2N$  lines, a new average value is computed. For the first  $2N$  lines, 0 is subtracted.

The size of the window and horizontal position are controlled by the `CCDC_CLAMP` register. The vertical position of the window is set to line 0 and cannot be modified:

- `CCDC_CLAMP[30:28] OBSLEN` sets the horizontal size of the window (1, 2, 4 or 8 pixels).
- `CCDC_CLAMP[27:25] OBSLN` sets the vertical size of the window ( $2N = 1, 2, 4$  or 8 lines).
- `CCDC_CLAMP[24:10] OBST` sets the horizontal start position of the upper-left corner of the window. It is specified from the start of the HS sync pulse in pixel clocks.

The gain factor is set by the `CCDC_CLAMP[4:0] OBGAIN` bit field. Its fixed-point representation is U5Q4; the range is 0 to 1.9375. The gain factor reset value is 1.

If optical-black clamping is disabled, digital clamp is enabled.

#### 12.5.5.6.2.3 Black Compensation

Black compensation applies an offset to the raw image data. The offset is applied according to the phase and color for each phase. The black compensation offsets are controlled by the `CCDC_BLKCOMP` register. All offsets are coded in S8Q0 representation (two's complement); the range is -128 to +127.

#### 12.5.5.6.2.4 Faulty-Pixel Correction

Faulty-pixel correction is enabled by setting the `CCDC_FPC[15]` FPCEN bit to 1. Before activating faulty-pixel correction, set the number of faulty pixels to be corrected in a frame with the `CCDC_FPC[14:0]` FPNUM bit field, set the faulty-pixel LUT in memory, and set the `CCDC_FPC_ADDR` register to the LUT address. The address should be aligned to a 64-bit byte boundary; the 6 LSBs are ignored. Reading the register always shows the 6 LSBs as 0.

If the CCDC module cannot fetch the required faulty-pixel entry in time, an error is set in the `CCDC_FPC[16]` FPERR bit. After the bit is set, no more faulty pixels are corrected in the frame. The bit is automatically cleared on the end of the frame and the feature reenables for the following frame.

#### 12.5.5.6.2.5 Data Formatter

The data formatter transforms movie mode readout patterns into Bayer readout patterns. It is enabled by setting `CCDC_FMTCFG[0]` FMTEN to 1.

The `CCDC_FMT_HORZ` and `CCDC_FMT_VERT` registers set a clip window at the input of the data reformatter.

The data formatter converts a single line of movie mode sensor into multiple Bayer lines; it is capable of transforming 1 input line into 1, 2, 3, or 4 output lines. The number of lines generated from one input line is set by the `CCDC_FMTCFG[3:2]` LNUM bit field. The following limitations apply:

- The maximum number of pixels that can be supported in an output line if the input line is transformed into 1 output line is 4x1376 (1376 is the limit of the line memory).
- The maximum number of pixels that can be supported in an output line if the input line is transformed into 2 output lines is 2x1376.
- The maximum number of pixels that can be supported in an output line if the input line is transformed into 3 output lines is 1376.
- The maximum number of pixels that can be supported in an output line if the input line is transformed into 4 output lines is 1376.

The data reformatter gets its flexibility from up to 8 different addresses and a program that can contain up to 16 entries each for the odd and even lines. The program length for even fields is set with the `CCDC_FMTCFG[11:8]` PLEN\_EVEN bit field. The program length for odd fields is set with the `CCDC_FMTCFG[7:4]` PLEN\_ODD bit fields. Each entry refers to one of the 8 addresses and supports autoincrement and autodecrement.

- The 8 addresses are controlled by the `CCDC_FMT_ADDR_i` registers (i = 0 to 7).
- The 16 program entries for even lines are controlled by the `CCDC_PRGEVEN0` and `CCDC_PRGEVEN1` registers. The 16 program entries for odd lines are controlled by the `CCDC_PRGODD0` and `CCDC_PRGODD1` registers.

Modulo addressing is used to access the program entries. Even input lines use the even program and odd input lines use the odd program. Each new pixel in a line uses one program entry.

The `CCDC_VP_OUT` register sets the frame size at the output of the video port.

#### Example 1: Conventional readout pattern: 1 input line = 1 output line

The following input-to-output mapping (see [Table 12-52](#)) corresponds to a conventional readout pattern. One input line corresponds to 1 output line; the output can be as large as 4x1376 pixels.

**Table 12-52. Conventional Readout Pattern 1 to 1**

Input	Pixels order in input line								
Line [i]	0	1	2	3	[...]	5500	5501	5502	5503
Output	Pixels order in output line								
Line [i]	0	1	2	3	[...]	5500	5501	5502	5503

To obtain this mapping between the input and output pixels, the following settings apply:

- **CCDC\_FMTCFG** [3:2] LNUM = 0 Converts to 1 line
- **CCDC\_FMTCFG** [11:8] PLEN\_EVEN = 0 1 program entry
- **CCDC\_FMTCFG** [7:4] PLEN\_ODD = 0 1 program entry
- **CCDC\_FMT\_ADDR\_i** [25:24] LINE (i = 0) = 0 Init ADDR0 pointer to 0th line
- **CCDC\_FMT\_ADDR\_i** [12:0] INIT (i = 0) = 0 Init ADDR0 index to 0th pixel
- **CCDC\_PRGEVEN0** [3:0] EVEN0 = 0 Even prog entry 0: ADDR0++
- **CCDC\_PRGODD0** [3:0] ODD0 = 0 Odd prog entry 0: ADDR0++
- **CCDC\_VP\_OUT** [3:0] HORZ\_ST = 0 Horizontal start
- **CCDC\_VP\_OUT** [16:4] HORZ\_NUM = 0 Horizontal size

The program for even and odd lines is executed as follows. Because there is only one program entry, this instruction is executed repeatedly.

```

ADDR0= (0, 0)
While not end_of_line
{
Write incoming pixel to ADDR0
ADDR0+=(1,0)
}
    
```

### Example 2: Dual readout pattern: 1 input line = 1 output line

The following input-to-output mapping (see [Table 12-53](#)) corresponds to a conventional dual readout pattern. One input line corresponds to 1 output line; the output can be as large as 4x1376 pixels.

**Table 12-53. Dual Readout Pattern 1 to 1**

Input	Pixels order in input line									
Line [i]	0	1	2	3	[...]	4092	4093	4094	4095	
Output	Pixels order in output line									
Line [i]	0	2	4	6	[...]	7	5	3	1	

To obtain this mapping between the input and output pixels, the following settings apply:

- **CCDC\_FMTCFG** [3:2] LNUM = 0 Converts to 1 line
- **CCDC\_FMTCFG** [11:8] PLEN\_EVEN = 1 2 program entry
- **CCDC\_FMTCFG** [7:4] PLEN\_ODD = 1 2 program entry
- **CCDC\_FMT\_ADDR\_i** [25:24] LINE (i = 0) = 0 Init ADDR0 pointer to 0th line
- **CCDC\_FMT\_ADDR\_i** [12:0] INIT (i = 0) = 0 Init ADDR0 index to 0th pixel
- **CCDC\_FMT\_ADDR\_i** [25:24] LINE (i = 1) = 0 Init ADDR1 pointer to 0th line
- **CCDC\_FMT\_ADDR\_i** [12:0] INIT (i = 1) = 4095 Init ADDR1 index to 4095th pixel
- **CCDC\_PRGEVEN0** [3:0] EVEN0 = 0 Even prog entry 0: ADDR0++
- **CCDC\_PRGEVEN0** [7:4] EVEN1 = 3 Even prog entry 1: ADDR1-
- **CCDC\_PRGODD0** [3:0] ODD0 = 0 Even prog entry 0: ADDR0++
- **CCDC\_PRGODD0** [7:4] ODD1 = 3 Even prog entry 1: ADDR1-
- **CCDC\_VP\_OUT** [3:0] HORZ\_ST = 0 Horizontal start
- **CCDC\_VP\_OUT** [16:4] HORZ\_NUM = 0 Horizontal size

```

ADDR0=(0,0)
ADDR1=(4095,0)
While not end_of_line
{
Write incoming pixel to ADDR0
ADDR0+= (1,0)
}
    
```

```
Write incoming pixel to ADDR1
ADDR1 --(1,0)
}
```

### Example 3: Dual readout pattern: 1 input line = 3 output line

The following input-to-output mapping (see [Table 12-54](#)) corresponds to a complex pattern. One input line corresponds to 3 output lines; the output can be as large as 1376 pixels.

**Table 12-54. Dual Readout Pattern 1 to 3**

Input	Pixels order in input line								
Line [i]	0	1	2	3	4	5	6	7	8
	9	10	11	[...]					
Output	Pixels order in output line								
Line [3i]			0	6	[...]	23	17	11	5
Line [3i + 1]		2	8	14	[...]	15	9	3	
Line [3i + 2]	4	10	16	22	[...]	7	1		

To obtain this mapping between the input and output pixels, the following settings apply:

- [CCDC\\_FMTCFG](#) [3:2] LNUM = 2 Converts to 3 lines
- [CCDC\\_FMTCFG](#) [11:8] PLEN\_EVEN = 5 6 program entries
- [CCDC\\_FMTCFG](#) [7:4] PLEN\_ODD = 5 6 program entries
- [CCDC\\_FMT\\_ADDR\\_i](#) [25:24] LINE (i = 0) = 0 Init ADDR0 pointer to 0th line
- [CCDC\\_FMT\\_ADDR\\_i](#) [12:0] INIT (i = 0) = 2 Init ADDR0 index to 2nd pixel
- [CCDC\\_FMT\\_ADDR\\_i](#) [25:24] LINE (i = 1) = 2 Init ADDR1 pointer to 2nd line
- [CCDC\\_FMT\\_ADDR\\_i](#) [12:0] INIT (i = 1) = 855 Init ADDR1 index to 855th pixel
- [CCDC\\_FMT\\_ADDR\\_i](#) [25:24] LINE (i = 2) = 1 Init ADDR2 pointer to first line
- [CCDC\\_FMT\\_ADDR\\_i](#) [12:0] INIT (i = 2) = 1 Init ADDR2 index to first pixel
- [CCDC\\_FMT\\_ADDR\\_i](#) [25:24] LINE (i = 3) = 1 Init ADDR3 pointer to first line
- [CCDC\\_FMT\\_ADDR\\_i](#) [12:0] INIT (i = 3) = 856 Init ADDR3 index to 856th pixel
- [CCDC\\_FMT\\_ADDR\\_i](#) [25:24] LINE (i = 4) = 2 Init ADDR4 pointer to second line
- [CCDC\\_FMT\\_ADDR\\_i](#) [12:0] INIT (i = 4) = 0 Init ADDR4 index to 0th pixel
- [CCDC\\_FMT\\_ADDR\\_i](#) [25:24] LINE (i = 5) = 0 Init ADDR5 pointer to 0th line
- [CCDC\\_FMT\\_ADDR\\_i](#) [12:0] INIT (i = 5) = 857 Init ADDR5 index to 857th pixel
- [CCDC\\_PRGEVEN0](#) [3:0] EVEN0 = 0 Even prog entry 0: ADDR0++
- [CCDC\\_PRGEVEN0](#) [7:4] EVEN1 = 3 Even prog entry 1: ADDR1- -
- [CCDC\\_PRGEVEN0](#) [11:8] EVEN2 = 4 Even prog entry 2: ADDR2++
- [CCDC\\_PRGEVEN0](#) [15:12] EVEN3 = 7 Even prog entry 3: ADDR3- -
- [CCDC\\_PRGEVEN0](#) [19:16] EVEN4 = 8 Even prog entry 4: ADDR4++
- [CCDC\\_PRGEVEN0](#) [23:20] EVEN5 = 11 Even prog entry 4: ADDR5- -
- [CCDC\\_PRGODD0](#) [3:0] ODD0 = 0 Even prog entry 0: ADDR0++
- [CCDC\\_PRGODD0](#) [7:4] ODD1 = 3 Even prog entry 1: ADDR1- -
- [CCDC\\_PRGODD0](#) [11:8] ODD2 = 4 Even prog entry 2: ADDR2++
- [CCDC\\_PRGODD0](#) [15:12] ODD3 = 7 Even prog entry 3: ADDR3- -
- [CCDC\\_PRGODD0](#) [19:16] ODD4 = 8 Even prog entry 4: ADDR4++
- [CCDC\\_PRGODD0](#) [23:20] ODD5 = 11 Even prog entry 4: ADDR5- -
- [CCDC\\_VP\\_OUT](#) [3:0] HORZ\_ST = 2 Horizontal start, excludes first 2 pixels
- [CCDC\\_VP\\_OUT](#) [16:4] HORZ\_NUM = 854 Horizontal size

```

ADDR0=(2,0)
ADDR1=(855,2)
ADDR2=(1,1)
ADDR3=(856,1)
ADDR4=(0,2)
ADDR5=(857,0)
While not end_of_line
{
Write incoming pixel to ADDR0
ADDR0 += (1, 0)
Write incoming pixel to ADDR1
ADDR1 -= (1, 0)
Write incoming pixel to ADDR2
ADDR2 += (1, 0)
Write incoming pixel to ADDR3
ADDR3 -= (1, 0)
Write incoming pixel to ADDR4
ADDR4 += (1, 0)
Write incoming pixel to ADDR5
ADDR5 -= (1, 0)
}
    
```

### Video Port

The 10-bit video-port output is enabled with `CCDC_FMTCFG[15] VPEN = 1`. Because the input data can be up to 12 bits, one must select which 10 bits are selected with `CCDC_FMTCFG[14:12] VPIN`.

The output of the video port goes to the Preview module. At the output of the video port, the data rate is resynchronized; the `CCDC_FMTCFG[18:16] VPIF_FRQ` bit field selects the video-output data rate as:  $L3 \text{ speed} / (\text{CCDC\_FMTCFG}[18:16] \text{VPIF\_FRQ} + 2)$  (from L3 speed/2 MHz to L3 speed/8 MHz). If `CCDC_FMTCFG[18:16] VPIF_FRQ` frequency is set too low compared to the input pixel clock, overflow can occur.

### 12.5.5.6.2.6 Output Formatter

#### 12.5.5.6.2.6.1 Low-Pass Filter

The low-pass filter is enabled with the `CCDC_SYN_MODE[14] LPF` bit. When enabled, two pixels each in the left and right edges of each line are cropped from the output.

#### 12.5.5.6.2.6.2 A-Law Compression

A-Law compression is enabled by setting `CCDC_ALAW [3] CCDTBL` to 1. The A-Law table is fixed, so no setup is required. When the input is wider than 10 bits, the `CCDC_ALAW [2:0] GWDI` bit is used to select which 10 bits of the 12 possible bits are selected for compression. See [Table 12-55](#).

**Table 12-55. CCDC\_ALAW [2:0] GWDI**

GWDI	Description
4	Bits 11 to 2
5	Bits 10 to 1
6	Bits 9 to 0
Others	Reserved

#### 12.5.5.6.2.6.3 Culling

Culling performs a horizontal and vertical decimation function. The horizontal and vertical culling patterns are set by the `CCDC_CULLING` register.

- The 8-bit `CCDC_CULLING[31:24] CULHEVN` and `CCDC_CULLING [23:16] CULHODD` bit fields set the horizontal culling pattern for even and odd lines. A 1 means that the pixel is retained; a 0 means that the pixel is skipped. The same number of retained pixels must be set for even and odd lines.

- The 8-bit **CCDC\_CULLING**[7:0] CULV bit field sets the vertical culling pattern. The LSB represents the top line and the MSB represents the bottom line. A 1 means that the line is retained; a 0 means that the line is skipped.

**12.5.5.6.2.6.4 Data Packing**

Pixel data are stored to memory in little-endian format (bytes at lower addresses have lower significance). By default, pixel data are stored in 16-bit words; unused bits are filled with zeros.

If the input data is 8 bits, or if A-Law compression is enabled, the data can be stored in 8-bit words by setting the **CCDC\_SYN\_MODE**[11] PACK8 bit to 1.

If the input data is 12, 11, 10, or 9 bits, and A-Law compression is not enabled, the 8 MSBs are stored to memory.

Figure 12-109 shows data packing and pixel ordering.

**Figure 12-109. Data Packing - Pixel Ordering**

	3 1	2 4	1 5	0 7	0 0
12 bits	0	pix 1		0	pix 0
11 bits	0	pix 1		0	pix 0
10 bits	0		pix 1	0	
9 bits	0		pix 1	0	
8 bits	0		pix 1	0	
8 bits packed	pix3		pix 2	pix 1	pix 0

camisp-118

**12.5.5.6.2.6.5 Clipping Window**

Before data is stored in memory, a clipping window can be set; only a selected sensor area is stored to memory. Figure 12-110 shows the settings; only the white area is stored to memory.

- The valid-data horizontal start position is controlled with the **CCDC\_HORZ\_INFO**[30:16] SPH bit field. The valid-data vertical start position is controlled with the **CCDC\_VERT\_START** register. If the sensor is interlaced, the vertical start position for even and odd fields can be configured independently with the **CCDC\_VERT\_START** register. If the sensor is progressive, the **CCDC\_VERT\_START**[14:0] SLV1 bit field is ignored.
- The valid-data horizontal size is controlled with the **CCDC\_HORZ\_INFO**[14:0] NPH bit field. The horizontal size must be a multiple of 16 pixels. The valid-data vertical size is controlled with the **CCDC\_VERT\_LINES**[14:0] NLV register.

**Figure 12-110. Clipping Window Before Output to Memory**

camisp-119

#### 12.5.5.6.2.6.6 Output to Memory

The output formatter memory write enable is controlled by the [CCDC\\_SYN\\_MODE\[17\]](#) WEN bit. The output of the data reformatter can be written to memory by setting [CCDC\\_SYN\\_MODE\[18\]](#) VP2SDR to 1.

The pixel data at the output of the output formatter is written to the address given by the [CCDC\\_SDR\\_ADDR](#) register. The address should be aligned on a 32-byte boundary. The 5 LSBs are ignored. Reading the register always shows the 5 LSBs as 0.

A destination pitch can be set with the [CCDC\\_HSIZE\\_OFF](#) register. The offset must be a multiple of 32 bytes. The 5 LSBs are ignored. Reading the register always shows the 5 LSBs as 0. It is required for the pixel line length to be a multiple of 32 bytes to be stored in memory without holes.

The [CCDC\\_SDOFST](#) register controls how the pixels are stored to memory.

Data to be written to memory can be qualified by the external `cam_wen` signal. This feature can be enabled by setting the [CCDC\\_SYN\\_MODE\[5\]](#) EXWEN bit. The [CCDC\\_CFG \[8\]](#) WENLOG bit configures how the `cam_wen` signal is used with the internally generated valid signal.

The data can be swapped on a byte basis with the [CCDC\\_CFG\[12\]](#) BSWD bit.

If [CCDC\\_SYN\\_MODE\[13:12\]](#) INPMOD = 1, the MSB of the 8-bit chroma component can be inverted by setting [CCDC\\_CFG\[13\]](#) MSBINVI to 1.

### 12.5.5.7 Summary of Constraints

The following is a list of register configuration constraints to adhere to when programming the CCDIC. It can be used as a quick checklist. More detailed register setting constraints can be found in the individual register descriptions.

- If the memory output port is enabled, the memory output line offset and address should be on 32-byte boundaries.
- If faulty-pixel correction is enabled, the [CCDC\\_FPC\\_ADDR](#) address should be on a 64-byte boundary.
- External WEN cannot be used when the VP2SDR path is enabled.
- If the formatter is enabled, in line-alternating mode, the vertical start and end number should be even.
- The horizontal number for the video port must be = 1376\*4.
- If the video port is enabled, [CCDC\\_VP\\_OUT\[30:17\]](#) VERT\_NUM must be [CCDC\\_FMT\\_VERT\[12:0\]](#) FMTLNV.
- The video port must be enabled if the formatter is enabled.
- In YCC input mode:
  - The [CCDC\\_COLPTN](#) must be set to 0s.
  - The [CCDC\\_BLKCMP](#) must be set to 0s.
  - Faulty-pixel correction must be disabled.
  - The video port must be disabled.
  - The formatter must be disabled.
  - The VP2SDR must be disabled.
  - The low-pass filter must be disabled.
  - The A-Law must be disabled.
- In RAW input mode, the resizer output path should not be enabled.

### 12.5.6 Programming the Preview Engine

This section discusses issues related to software control of the preview engine. It lists which registers are required to be programmed in different modes, how to enable and disable the preview engine, and how to check the status of the preview engine; discusses the different register access types; and enumerates programming constraints.

#### 12.5.6.1 Preview Hardware Setup/Initialization

This section discusses the configuration of the preview engine required before image processing can begin.

##### 12.5.6.1.1 Reset Behavior

On hardware reset of the camera ISP, all registers in the preview engine are reset to their reset values. However, because the preview engine programmable tables (gamma, noise filter, luminance enhancer, and CFA coefficients) are stored in internal memory, their contents do not have reset values. If the reset is a chip-level power-on reset (reset after power is applied), the contents of these tables are unknown. If the reset is a camera ISP module reset (when power remains active), the contents of these tables remain the same as before the reset.

##### 12.5.6.1.2 Register Setup

Before enabling the preview engine, the hardware must be correctly configured through register writes. [Table 12-56](#) identifies the register parameters that must be programmed before enabling the preview engine.

**Table 12-56. Preview Engine Required Configuration Parameters**

Function	Configuration Required
Function enable/disable	<a href="#">PRV_PCR[5] INVALAW</a> <a href="#">PRV_PCR[7] DRKFCAP</a> <a href="#">PRV_PCR[6] DRKFEN</a> <a href="#">PRV_PCR[21] SCOMP_EN</a> <a href="#">PRV_PCR[8] HMEDEN</a> <a href="#">PRV_PCR[9] NFEN</a> <a href="#">PRV_PCR[10] CFAEN</a> <a href="#">PRV_PCR[26] GAMMA_BYPASS</a> <a href="#">PRV_PCR[15] YNENHEN</a> <a href="#">PRV_PCR[16] SUPEN</a> <a href="#">PRV_PCR[27] DCOREN</a>
I/O ports	<a href="#">PRV_PCR[2] SOURCE</a> <a href="#">PRV_PCR[20] SDRPORT</a> <a href="#">PRV_PCR[19] RSZPORT</a>

Write to memory	<a href="#">PRV_PCR</a> [20] SDRPORT = 0x1	<a href="#">PRV_WSDR_ADDR</a> <a href="#">PRV_WADD_OFFSET</a>

### 12.5.6.1.3 Table Setup

The three gamma memories, noise filter threshold memory, noise filter strength memory, luminance enhancer memory, and the CFA coefficient memory must be filled in before the operation of the preview engine, if their respective functions are enabled.

Two registers allow memory contents to be read and written:

- The address register is used to select the specific table entry: [PRV\\_SET\\_TBL\\_ADDR](#).
- The data register contains the data to be written to the specified location: [PRV\\_SET\\_TBL\\_DATA](#).

While the data register is 20 bits wide, only the 8 LSB data is used for the gamma, noise filter, and CFA filter tap memories.

The preview engine supports linear increments on reads and writes automatically. The following examples show how the programmer can read/write the memory. If data is read/written, the address pointer is automatically incremented. For random/noncontiguous reads/writes, [PRV\\_SET\\_TBL\\_ADDR](#) register must be modified.

---

**NOTE:** The address is not autoincremented when the preview engine is busy and users try to read/write the tables.

---

#### Example:

##### Read/write all the entries of the CFA table (using linear increment):

- WRITE (SET\_TBL\_ADDR, 0x1400);
- READ (SET\_TBL\_DATA, 0xvalue1);
- WRITE (SET\_TBL\_DATA, 0xvalue2);
- READ (SET\_TBL\_DATA, 0xvalue3);
- Etc. . . .
- READ (SET\_TBL\_DATA, 0xvalue163F);

**Read/write selective entries of the tables (have to program the address separately for each read/write)**

- WRITE (SET\_TBL\_ADDR, 11);
- READ (SET\_TBL\_DATA, value11);
- WRITE (SET\_TBL\_ADDR, 564);
- WRITE (SET\_TBL\_DATA, value564);

### 12.5.6.2 Enable/Disable Hardware

Setting the [PRV\\_PCR\[0\] ENABLE](#) bit to 0x1 enables the preview engine. This must be done after all required registers and tables are programmed.

When the input source is the memory, the preview engine always operates in one-shot mode. In other words, after enabling the preview engine, the ENABLE bit is automatically turned off (set to 0) and only a single frame is processed from memory. In this mode, fetching and processing of the frame begin immediately on setting the ENABLE bit.

When the input source is the CCDC, the preview engine can be configured to operate in either one-shot mode or continuous mode ([PRV\\_PCR \[3\] ONESHOT](#)). Processing of the frame is depends on the timing of the CCDC. To ensure that data from the CCDC is not missed, the preview engine must be enabled before the CCDC so that it waits for CCDC data.

---

**NOTE:** In one-shot mode, on setting the ENABLE bit, the processing of the frame begins and the ENABLE, ONESHOT, and SOURCE bits are reset to their reset values.

---

When the preview engine is in continuous mode, it can be disabled by clearing the ENABLE bit during the processing of the last frame. The disable is latched in at the end of the frame in which it is written.

### 12.5.6.3 Events and Status Checking

The preview engine generates an interrupt at the end of each frame.

The status of this interrupt can be checked by reading the [ISP\\_IRQ0STATUS](#) register (or [ISP\\_IRQ1STATUS](#)). When the read of the register [ISP\\_IRQ0STATUS](#) occurs (or [ISP\\_IRQ1STATUS](#)), the register is not automatically reset. To reset the interrupt, a 1 must be written to the PRV\_DONE\_IRQ bit.

Each event that generates an interrupt can be individually mapped to ARM or DSP using the [ISP\\_IRQ0ENABLE](#) register (or [ISP\\_IRQ1ENABLE](#)). When a particular event is not enabled (for example [ISP\\_IRQ0ENABLE\[x\] = 0](#)), the correspondent status ([ISP\\_IRQ0STATUS \[x\] = 1](#)) bit is flagged if the correspondent event occurs. This has no effect on the interrupt line, but can be used by software to poll the status.

The [PRV\\_PCR\[1\] BUSY](#) status bit is set when the start of frame occurs (if the [PRV\\_PCR\[0\] ENABLE](#) bit is 1 at that time). It is automatically reset to 0 at the end of a frame. The [PRV\\_PCR\[1\] BUSY](#) status bit may be polled to determine end-of-frame status.

The [PRV\\_PCR\[31\] DRK\\_FAIL](#) status bit is set when dark-frame data fetched from memory arrives late. This bit can be reset by writing a 1 to the bit.

### 12.5.6.4 Register Accessibility During Frame Processing

There are three types of register access in the preview engine.

- Shadow registers: These registers/fields can be read and written (if the field is writable) at any time. However, the written values take effect only at the start of a frame. Reads return the most recent write, even though the settings are not used until the next start of frame.

The shadowed registers are:

- [PRV\\_PCR](#)
- [PRV\\_RSDR\\_ADDR](#)

- [PRV\\_RADR\\_OFFSET](#)
- [PRV\\_DSDR\\_ADDR](#)
- [PRV\\_DRKF\\_OFFSET](#)
- [PRV\\_WSDR\\_ADDR](#)
- [PRV\\_WADD\\_OFFSET](#)
- Busy-writable registers: These registers/fields can be read or written even if the module is busy. Changes to the underlying settings occur instantaneously.  
The busy-writable registers are:
  - [PRV\\_WB\\_DGAIN](#)
  - [PRV\\_WBGAIN](#)
- Busy-lock registers:
  - All registers EXCEPT the shadow and busy-writable registers belong to this category. Busy-lock registers cannot be written when the module is busy. Writes are allowed, but no change occurs in the registers (blocked writes from hardware perspective, but allowed writes from software perspective).
  - After the [PRV\\_PCR\[1\]](#) BUSY bit is reset to 0, busy-lock registers can be written.
  - The [PRV\\_SET\\_TBL\\_DATA](#) register cannot be read when the preview engine is busy, because this register is mapped to memories internally. Such reads return indeterminate data. Byte enables are not implemented for reading preview engine memories.

The ideal procedure for changing the preview engine registers is:

```
IF (PRV\_PCR\[1\] BUSY == 0) OR IF
(EOF interrupt occurs)
    DISABLE PREVIEW ENGINE
    CHANGE REGISTERS
    ENABLE PREVIEW ENGINE
```

### 12.5.6.5 Interframe Operations

Between frames, it may be necessary to enable/disable functions or modify memory pointers. Because the [PRV\\_PCR](#) register and memory pointer registers are shadowed, these modifications can occur any time before the end of the frame, and the data is latched in for the next frame. The MPU subsystem can perform these changes on receiving an interrupt.

### 12.5.6.6 Summary of Constraints

The following is a list of register configuration constraints to adhere to when programming the preview engine. It can be used as a quick checklist. More detailed register setting constraints can be found in the individual register descriptions.

- A frame can only be read from memory when the SBL read port is affected to the PREVIEW module ([ISP\\_CTRL\[27\]](#) SBL\_SHARED\_RPORTA = 0)
- The shading compensation feature can only be used when the SBL read port is affected to the PREVIEW module ([ISP\\_CTRL\[28\]](#) SBL\_SHARED\_RPORTB = 0)
- If the memory output port is enabled, the memory output line offset and address should be on 32-byte boundaries.
- The output width must be less than or equal to 3312.
- The output width must be even.
- Input to the horizontal median filter must be even.
- Defect correction can only be used when noise filter is enabled
- Input height must be smaller than CCDC output height.
- The input width of the preview engine must be a multiple of the average count multiplied by the least

common multiple of the odd distance and even distance of the averager.

- $(\text{PRV\_HORZ\_INFO}[13:0] \text{ EPH} - \text{HORZ\_INFO}[29:16] \text{ SPH} + 1) \text{ MOD } ((1 \text{ PRV\_AVE}[1:0] \text{ COUNT}) * \text{LeastCommonMultiple}(\text{PRV\_AVE}[5:4] \text{ ODDDIST}+1, \text{PRV\_AVE}[3:2] \text{ EVENDIST}+1)) = 0$
- Input width must be at least 4 pixels smaller than CCDC output width:
  - $\text{PRV\_HORZ\_INFO}[29:16] \text{ SPH}$  at least 2 pixels before last pixel from CCDC
  - $\text{PRV\_HORZ\_INFO}[13:0] \text{ EPH}$  at least 2 pixels before last pixel from CCDC

## 12.5.7 Programming the Resizer

This section discusses issues related to software control of the resizer. It lists which registers are required to be programmed in different modes, how to enable and disable the resizer, and how to check the status of the resizer; discusses the different register access types; and enumerates programming constraints.

### 12.5.7.1 Resizer Hardware Setup/Initialization

This section discusses the configuration of the resizer required before image processing can begin.

#### 12.5.7.1.1 Reset Behavior

On hardware reset of the camera ISP, all registers in the resizer are reset to their reset values.

#### 12.5.7.1.2 Register Setup

Before enabling the resizer, the hardware must be correctly configured through register writes. [Table 12-58](#) identifies the register parameters that must be programmed before enabling the resizer.

**Table 12-58. Resizer Required Configuration Parameters**

Function	Configuration Required
Resizer control parameters	<a href="#">RSZ_CNT</a>
I/O sizes	<a href="#">RSZ_OUT_SIZE</a> <a href="#">RSZ_IN_START</a> <a href="#">RSZ_IN_SIZE</a>
Memory addresses	<a href="#">RSZ_SDR_INADD</a> <a href="#">RSZ_SDR_INOFF</a> <a href="#">RSZ_SDR_OUTADD</a> <a href="#">RSZ_SDR_OUTOFF</a>
Filter coefficients	<a href="#">RSZ_HFILT10</a> to <a href="#">RSZ_HFILT3130</a> <a href="#">RSZ_VFILT10</a> to <a href="#">RSZ_VFILT3130</a>
Edge enhancement	<a href="#">RSZ_YENH</a> [17:16] ALG0

The edge-enhancement function is optional:

- If it is disabled, the rest of the [RSZ\\_YENH](#) register does not need to be programmed.
- If it is enabled, the edge-enhancement parameters in [Table 12-59](#) must be programmed so that the edge-enhancement function operates correctly.

[Table 12-59](#) can be read as:

If (**Condition** is TRUE) then

**Configuration required** parameters must be programmed.

**Table 12-59. Resizer Conditional Configuration Parameters**

Function	Condition	Configuration Required
Edge enhancement	<a href="#">RSZ_YENH</a> [17:16] ALG0 = 0x1 or 0x2	<a href="#">RSZ_YENH</a> [15:12] GAIN <a href="#">RSZ_YENH</a> [11:8] SLOP <a href="#">RSZ_YENH</a> [7:0] CORE

### 12.5.7.2 Enable/Disable Hardware

Setting the [RSZ\\_PCR](#)[0] ENABLE bit to 0x1 enables the resizer. This must be done after all required registers are programmed.

When the input source is memory, the resizer always operates in one-shot mode. In other words, after enabling the resizer, the [RSZ\\_PCR](#)[0] ENABLE bit is automatically turned off (set to 0) and only a single frame is processed from memory.

In this mode, fetching and processing of the frame begin immediately on setting the [RSZ\\_PCR](#) [0] ENABLE bit.

When the input source is the CCD or preview engine, the resizer can be configured to operate in either one-shot mode, or continuous mode ([RSZ\\_PCR](#)[2] ONESHOT). Processing of the frame depends on the timing of the CCD/Preview. To ensure that data from the CCD or preview engine is not missed, the resizer must be enabled before to these upstream modules, so it waits for data from the CCD or the preview engine.

When the resizer is started during an ongoing frame the enable is latched at the end of the frame it was written in.

When the resizer is in continuous mode, it can be disabled by clearing the ENABLE bit during the processing of the last frame. The disable is latched in at the end of the frame in which it was written.

### 12.5.7.3 Events and Status Checking

The resizer generates an interrupt event at the end of each frame.

The status of this interrupt can be checked by reading the [ISP\\_IRQ0STATUS](#) register (or [ISP\\_IRQ1STATUS](#)). When the read of the register [ISP\\_IRQ0STATUS](#) occurs (or [ISP\\_IRQ1STATUS](#)), the register is not automatically reset. To reset the interrupt, a 1 must be written to the [RSZ\\_DONE\\_IRQ](#) bit.

Each event that generates an interrupt can be individually mapped to ARM or DSP using the [ISP\\_IRQ0ENABLE](#) register (or [ISP\\_IRQ1ENABLE](#)). When a particular event is not enabled (for example [ISP\\_IRQ0ENABLE](#)[x] = 0), the correspondent status ([ISP\\_IRQ0STATUS](#)[x] = 1) bit is flagged, if the correspondent event occurs. This has no effect on the interrupt line, but can be used by software to poll the status.

The [RSZ\\_PCR](#)[1] BUSY status bit is set when the start of frame occurs (if the [RSZ\\_PCR](#)[0] ENABLE bit is 1 at that time). It is automatically reset to 0 at the end of a frame. The [RSZ\\_PCR](#)[1] BUSY status bit may be polled to determine end-of-frame status in oneshot mode. [Figure 12-111](#) shows the firmware/hardware interaction. Configuration registers and filter coefficients are programmed in-between or before busy periods, before writing ENABLE to 0x1.

**Figure 12-111. Firmware Interactions for Memory-Input Resizing**

**NOTE:** The `SBL_SDR_REQ_EXP[19:10]` `RSZ_EXP` bit field enables the spreading of non-real time read requests over time. It is useful to avoid overflow situations when the resizer module is programmed to work from memory to memory.

#### 12.5.7.4 Register Accessibility During Frame Processing

There are two types of register access in the resizer.

- Shadow registers: These registers/fields can be read and written (if the field is writable) at any time. However, the written values take effect only at the start of a frame. Reads return the most recent write, even though the settings are not used until the next start of frame.

The shadowed registers are:

- `RSZ_PCR`
- `RSZ_SDR_INADD`
- `RSZ_SDR_INOFF`
- `RSZ_SDR_OUTADD`
- `RSZ_SDR_OUTOFF`
- Busy-lock registers
  - All registers EXCEPT the shadowed registers belong to this category.
  - Busy-lock registers cannot be written when the module is busy. Writes are allowed, but no change occurs in the registers (blocked writes from hardware perspective; allowed write from software perspective).
  - After the `RSZ_PCR[1] BUSY` bit is reset to 0, the busy-lock registers can be written.

The ideal procedure for changing the resizer registers is:

```
IF (RSZ_PCR[1] BUSY == 0) OR IF
(EOF interrupt occurs)
    DISABLE RESIZER
    CHANGE REGISTERS
    ENABLE RESIZER
```

#### 12.5.7.5 Inter-Frame Operations

Between frames, it may be necessary to modify the memory pointers before processing the next frame. Because the `RSZ_PCR[0] ENABLE` bit and memory pointer registers are shadowed, these modifications can occur any time before the end of the frame, and the data is get latched in for the next frame. The MPU subsystem can perform these changes on receiving an interrupt.

---

**NOTE:** The firmware is responsible for computing and uploading the filter coefficients. If polyphase resampling is used, a different set is required when changing between 4-tap and 7-tap modes, and with different downsampling factors; all upsampling factors can share the same set of coefficients. Do not change any busy-lock registers while the resizer is operating. Specifically, when back-to-back resizes require changes in any busy-lock registers (such as the coefficients, resizing ratios, input and output sizes), users must wait for the first resize to complete. The following section describes some scenarios where this is required.

---

#### 12.5.7.5.1 Multiple Passes for Large Resizing Operations

The resizer supports multiple passes of processing for large resizing operations. "Large" has the following meanings:

- Wider output than 3312 pixels: This works only in memory input mode. Input can be partitioned into multiple resizer blocks, and each block is separately resized and stitched together. Having input/output memory line offsets, input starting pixel and starting phase are essential to make this work. The basic idea is to begin subsequent slices at exactly where previous images leave off. The starting phase and pixel registers can be programmed to this exact location.
- Larger than 4x upsampling: Resizing can be applied in multiple passes. For example, 10x upsampling can be realized by first a 4x upsampling, then a 2.5x upsampling. The first pass can be performed on-the-fly with the preview engine. The second pass can be performed only with input from memory, and for 10x digital zoom; there is time outside the active picture region to perform the second pass.
- Larger than 4:1 downsampling: Although it is rarely necessary to generate a very small image from a large image, this is supported by the hardware. For example, 10x downsampling can be realized first with 4x downsampling on-the-fly with the preview engine, then 2.5x downsampling in the memory-input path. There may not be much time outside the active data region for the second pass, but since the image is already reduced to 1/16 of its original size, not much time is necessary. Typically, sensor or video input has 10 ~ 20 % of usable vertical blanking.

For all these scenarios, the second pass can be configured and initiated from an interrupt service routine triggered by the resizer end-of-frame interrupt: [ISP\\_IRQ0ENABLE\[24\]](#) RSZ\_DONE\_IRQ (or [ISP\\_IRQ1ENABLE](#)).

#### 12.5.7.5.2 Processing Time Calculation

The time calculated below is the time it takes for all resizes where the input source is memory (second pass when doing a 10x resize in preview mode; in the case of a 10x resize in preview mode, the first pass is hidden behind the time it takes to capture and process the image from the sensor based on cam\_pclk and the number of lines resized).

The following equation can be used to determine the processing time of the resizer when the input is from memory and therefore how much time it takes before it can switch back to preview input mode:

$$\text{Time} = [W \times \text{bytes\_per\_pixel} \times H] / [L3 / 2]$$

Where:

/\* If the input is YUV422 and horizontal downsampling is performed: \*/

if (([RSZ\\_CNT\[27\]](#) INPTYP ==0) (([RSZ\\_CNT\[9:0\]](#) HRSZ + 1) 256))

W = average (input\_width, output width); /\* output width includes extra 4 pixels if edge enhancement is enabled\*/

else

W = max(input width, output width); /\*output width includes extra 4 pixels if edge enhancement is enabled\*/

$$\begin{aligned}
 \text{input\_width} &= \text{RSZ\_IN\_SIZE}[12:0]\text{HORZ} \\
 \text{output\_width} &= \text{RSZ\_OUT\_SIZE}[11:0]\text{HORZ} \\
 \text{input\_height} &= \text{RSZ\_IN\_SIZE}[28:16]\text{VERT} \\
 \text{bytes\_per\_pixel} &= \begin{cases} 1, & \text{when } \text{RSZ\_CNT}[27]\text{INPTYP} = 1 \text{ (color separate)} \\ 2, & \text{when } \text{RSZ\_CNT}[27]\text{INPTYP} = 0 \text{ (YUV422)} \end{cases}
 \end{aligned}$$

camisp-E097

This time is the baseline steady state calculation of the hardware and does not include the time it takes for the hardware to fetch the first input and fill the pipeline. It also does not include the time spent from the last output from the resizer to get back to memory when the resizer interrupt occurs.

However, these beginning and ending times are relatively negligible.

Depending on real-time constraints, this processing time may be much faster than is required. (data fetches can be delayed from memory to free more bandwidth for use by other system peripherals; see [Section 12.5.10.5.2, Input from Memory](#).)

### 12.5.7.6 Summary of Constraints

The following is a list of register configuration constraints to adhere to when programming the resizer. It can be used as a quick checklist. More detailed register setting constraints can be found in the individual register descriptions.

- Vertical and horizontal resize ratio values must be within the following range: [64..1024].
- Output width:
  - Must be within the maximum limit:
    - width 3312 (if vertical resize value is in range:  $(\text{RSZ\_CNT}[19:10] \text{ VRSZ} + 1) = [64..512]$ )
    - width 1650 (if vertical resize value is in range:  $(\text{RSZ\_CNT}[19:10] \text{ VRSZ} + 1) = [513..1024]$ )
  - Must be even
  - Must be a multiple of 16 bytes (for vertical upsizing)
- When input is from preview engine/CCDC:
  - The input height and width must be = the output of the preview engine/CCDC.
  - The input address and offset must be zero.
  - The input can not be color-separated data.
- If the source is memory:
  - The vertical start pixel must be zero.
  - The horizontal start pixel must be within the range: 0:15 for color interleaved, 0:31 for color separate data.
  - The memory output line offset and address must be on 32-byte boundaries.
- Input height and width MUST adhere to the equations in [Table 12-60](#).

**Table 12-60. How to Set Input Height and Width**

	8-phase, 4-tap mode	4-phase, 7-tap mode
<a href="#">RSZ_IN_SIZE</a> [12:0] HORZ	$(32 * \text{sph} + (\text{ow} - 1) * \text{hrsz} + 16) 8 + 7$	$(64 * \text{sph} + (\text{ow} - 1) * \text{hrsz} + 32) 8 + 7$
<a href="#">RSZ_IN_SIZE</a> [28:16] VERT	$(32 * \text{spv} + (\text{oh} - 1) * \text{vrsz} + 16) 8 + 4$	$(64 * \text{spv} + (\text{oh} - 1) * \text{vrsz} + 32) 8 + 7$

Where:

- sph = Start phase horizontal ([RSZ\\_CNT\[22:20\]](#) HSTPH)
- spv = Start phase vertical ([RSZ\\_CNT\[25:23\]](#) VSTPH)
- ow = Output width ([RSZ\\_OUT\\_SIZE\[11:0\]](#) HORZ + extra)
- oh = Output height ([RSZ\\_OUT\\_SIZE\[27:16\]](#) VERT)
- hrsz = Horizontal resize value ([RSZ\\_CNT\[9:0\]](#) HRSZ + 1)
- vrsz = Vertical resize value ([RSZ\\_CNT\[19:10\]](#) VRSZ + 1)
- extra = 0 when [RSZ\\_YENH\[17:16\]](#) ALGO = 0 (edge enhancement disabled)
- extra = 4 when [RSZ\\_YENH\[17:16\]](#) ALGO != 0 (edge enhancement enabled)

---

**NOTE:** Normally, (for example, for a QVGA display or encoded PAL video), the output size, not the input size, matters. The image provided by preview/CCDC/memory must have an adequate output size: at least [RSZ\\_IN\\_SIZE\[12:0\]](#) HORZ x [RSZ\\_IN\\_SIZE\[28:16\]](#) VERT. If the image is bigger, the resizer can crop extra pixels.

The phase is usually computed to keep the center of the image at the same location. This permits a natural-looking continuous digital zoom.

For this reason, [Table 12-60](#) explains how to compute [RSZ\\_IN\\_SIZE\[12:0\]](#) HORZ , [RSZ\\_IN\\_SIZE\[28:16\]](#) VERT, not how to compute the output size.

---

## 12.5.8 Programming the H3A

This section discusses issues related to software control of the H3A module. It lists which registers are required to be programmed in different modes, how to enable and disable the H3A, and how to check the status of the H3A. It also discusses the different register access types and enumerates programming constraints.

### 12.5.8.1 Hardware Setup/Initialization

This section discusses the configuration of the H3A required before image processing can begin.

#### 12.5.8.1.1 Reset Behavior

On hardware reset of the camera ISP, all registers in the H3A are reset (set to their reset values).

#### 12.5.8.1.2 Register Setup

For register configuration, the AF engine and the AEW engine of the H3A can be independently be configured. Because there are separate enable bits for each engine, so this section discusses the AF engine and the AEW engine separately.

##### 12.5.8.1.2.1 AF Engine

Before enabling the AF engine, the hardware must be correctly configured through register writes. [Table 12-61](#) identifies the register parameters that must be programmed before enabling the AF engine of the H3A.

**Table 12-61. AF Engine Required Configuration Parameters**

Function	Configuration Required
AF optional preprocessing	<a href="#">H3A_PCR[2]</a> AF_MED_EN <a href="#">H3A_PCR[1]</a> AF_ALAW_EN
AF mode configuration	<a href="#">H3A_PCR[13:11]</a> RGBPOS <a href="#">H3A_PCR[14]</a> FVMODE

**Table 12-61. AF Engine Required Configuration Parameters (continued)**

Function	Configuration Required
Paxel start and size information	<a href="#">H3A_AFPAX1</a>
	<a href="#">H3A_AFPAX2</a>
	<a href="#">H3A_AFPAXSTART</a>
	<a href="#">H3A_AFIIRSH</a>
Memory address	<a href="#">H3A_AFBUFST</a>
Filter coefficients	<a href="#">H3A_AFCOE010</a> to <a href="#">H3A_AFCOE1010</a>

The horizontal median filter function is optional.

If it is disabled, the [H3A\\_PCR\[10:3\] MED\\_TH](#) does not need to be programmed.

However, if it is enabled, the [H3A\\_PCR\[10:3\] MED\\_TH](#) parameter must be programmed so that the horizontal median filter function operates correctly.

[Table 12-62](#) can be read as:

If (**Condition** is TRUE) then

**Configuration required** parameters must be programmed

**Table 12-62. AF Engine Conditional Configuration Parameters**

Function	Condition	Configuration Required
Horizontal median filter	<a href="#">H3A_PCR[2] AF_MED_EN</a>	<a href="#">H3A_PCR[10:3] MED_TH</a>

### 12.5.8.1.2.2 AEW Engine

Before enabling the AEW engine, the hardware must be correctly configured through register writes.

[Table 12-63](#) identifies the register parameters that must be programmed before enabling the AEW engine of the H3A.

**Table 12-63. AEW Engine Required Configuration Parameters**

Function	Configuration Required
AEW optional preprocessing	<a href="#">H3A_PCR[17] AEW_ALAW_EN</a>
Saturation limit	<a href="#">H3A_PCR[31:22] AVE2LMT</a>
Window start and size information	<a href="#">H3A_AEWWIN1</a>
	<a href="#">H3A_AEWINSTART</a>
	<a href="#">H3A_AEWINBLK</a>
	<a href="#">H3A_AEWSUBWIN</a>
Memory address	<a href="#">H3A_AEWBUFST</a>

### 12.5.8.2 Enable/Disable Hardware

Setting the [H3A\\_PCR\[0\] AF\\_EN](#) bit enables the AF engine, and the [H3A\\_PCR\[16\] AEW\\_EN](#) bit enables the AEW engine. This should be done after all required registers are programmed.

The H3A always operates in continuous mode. Because the input to the H3A module is the video-port interface of the CCDIC, processing of the frame depends on the timing signals from the CCDIC. To ensure that data from the CCDIC is not missed, the H3A should be enabled before the CCDIC so that it waits for CCDIC data.

The AF engine or the AEW engine can be disabled by clearing the [H3A\\_PCR\[0\] AF\\_EN](#) or [H3A\\_PCR \[16\] AEW\\_EN](#) bit, respectively, during the processing of the last frame. The disable is latched in at the end of the frame in which it is written.

### 12.5.8.3 Event and Status Checking

Both the AF engine and the AEW engine generate an interrupt at the end of processing each frame. These interrupt events can be sent to CAM\_IRQ0 or CAM\_IRQ1 by setting the H3A\_AWB\_DONE\_IRQ or H3A\_AF\_DONE\_IRQ bits in the [ISP\\_IRQ0ENABLE](#) enable register (or [ISP\\_IRQ1ENABLE](#)).

The status of these interrupts can be checked by reading the [ISP\\_IRQ0STATUS](#) register (or [ISP\\_IRQ1STATUS](#)). When the read of the register [ISP\\_IRQ0STATUS](#) occurs (or [ISP\\_IRQ1STATUS](#)), the register is not automatically reset. To reset the interrupt, a 1 must be written to the corresponding bit.

Each event that generates an interrupt can be individually mapped to ARM or DSP using the [ISP\\_IRQ0ENABLE](#) register (or [ISP\\_IRQ1ENABLE](#)). When a particular event is not enabled (for example [ISP\\_IRQ0ENABLE\[x\] = 0](#)), the correspondent status ([ISP\\_IRQ0STATUS \[x\] = 1](#)) bit is flagged if the correspondent event occurs. This has no effect on the interrupt line, but can be used by software to poll the status.

### 12.5.8.4 Register Accessibility During Frame Processing

There are two types of register access in the H3A module:

- Shadow registers: These registers/fields can be read and written (if the field is writable) at any time. However, the written values take effect only at the start of a frame. Reads return the most recent write, even though the settings are not used until the next start of frame.

The shadowed registers are:

- [H3A\\_PCR](#)
- [H3A\\_AFBUFST](#)
- [H3A\\_AEWBUFST](#)

- Busy-lock registers:

- All registers EXCEPT the shadowed registers belong to this category.
- Busy-lock registers cannot be written when the module is busy. Writes are allowed, but no change occurs in the registers (blocked writes from hardware perspective, but allowed writes from software perspective).
- After the busy bit in the PCR register is reset to 0, the busy-lock registers can be written ([H3A\\_PCR \[15\] BUSYAF](#) for AF registers and [H3A\\_PCR \[18\] BUSYAEAWB](#) for AE/AWB registers).

The ideal procedure for changing the H3A registers is:

```
IF (H3A\_PCR \[15\] BUSYAF == 0 OR H3A\_PCR \[18\] BUSYAEAWB == 0) OR IF (EOF interrupt occurs)
    DISABLE AF or AE/AWB
    CHANGE REGISTERS AF or AE/AWB
    ENABLE AF or AE/AWB
```

### 12.5.8.5 Interframe Operations

Between frames, it may be necessary to modify the memory pointers before processing the next frame. Since the [H3A\\_PCR](#) and memory pointer registers are shadowed, these modifications can occur any time before the end of the frame, and the data is latched in for the next frame. The MPU subsystem can perform these changes on receiving an interrupt.

### 12.5.8.6 Summary of Constraints

The following is a list of register configuration constraints to adhere to when programming the H3A. It can be used as a quick checklist. More detailed register setting constraints can be found in the individual register descriptions.

- The output addresses must be on 64-byte boundaries.  
AF Engine:
- The pixel horizontal start value must be greater than or equal to the IIR horizontal start position.

- The width and height of the paxels must be even numbers.
- The minimum width of the autofocus paxel must be 6 pixels.
- Paxels cannot overlap the last pixel in a line.
- Paxels must be adjacent to one another.

AEW Engine:

- The width and height of the windows must be even numbers.
- Subsampling windows can only start on even numbers.
- The minimum width of the AE/AWB windows is 6 pixels.

### 12.5.9 Programming the Histogram

This section discusses issues related to software control of the histogram module. It lists which registers are required to be programmed in different modes, how to enable and disable the histogram, and how to check the status of the histogram; discusses the different register access types; and enumerates programming constraints.

#### 12.5.9.1 Hardware Setup/Initialization

This section discusses the configuration of the histogram required before image processing can begin.

##### 12.5.9.1.1 Reset Behavior

On hardware reset of the camera ISP, all registers in the histogram are reset to their reset values. However, since the histogram output memory is stored in internal memory, its contents do not have reset values. If the reset is a chip-level power-on reset (reset after power is applied), the contents of this memory are unknown. If the reset is a camera ISP module reset (when power remains active), the contents of this memory remain the same as before the reset.

##### 12.5.9.1.2 Reset of Histogram Output Memory

Clear the output memory before enabling the histogram. This can be done two ways:

- Writing zeros to the memory through software
- If the [HIST\\_CNT](#) [7] CLR bit is set, reading the memory causes it to be reset after the read.

Reads and writes to the output memory are blocked when the [HIST\\_PCR](#) [1] BUSY bit is 1.

##### 12.5.9.1.3 Register Setup

Before enabling the histogram module, the hardware must be correctly configured through register writes. [Table 12-64](#) identifies the register parameters that must be programmed before enabling the histogram.

**Table 12-64. Histogram Required Configuration Parameters**

Function	Configuration Required
Histogram Control Bits	<a href="#">HIST_CNT</a> [3] SOURCE <a href="#">HIST_CNT</a> [6] CFA <a href="#">HIST_CNT</a> [5:4] BINS <a href="#">HIST_CNT</a> [2:0] SHIFT <a href="#">HIST_CNT</a> [7] CLR
White Balance Gain	<a href="#">HIST_WB_GAIN</a>
Region n Size and position (n = 0)	<a href="#">HIST_Rn_HORZ</a> <a href="#">HIST_Rn_VERT</a>

Table 12-65 can be read as:

If (**Condition** is TRUE) then

**Configuration required** parameters should be programmed

**Table 12-65. Histogram Conditional Configuration Parameters**

Function	Condition	Configuration Required
Input from memory	<a href="#">HIST_CNT</a> [3] SOURCE = 0x1	<a href="#">HIST_CNT</a> [8] DATSIZ <a href="#">HIST_RADD</a> <a href="#">HIST_RADD_OFF</a> <a href="#">HIST_H_V_INFO</a>
Less than 256 bins	<a href="#">HIST_CNT</a> [5:4] BINS 3	<a href="#">HIST_Rn_HORZ</a> (n = 1) <a href="#">HIST_Rn_VERT</a> (n = 1)
Less than 128 bins	<a href="#">HIST_CNT</a> [5:4] BINS 2	<a href="#">HIST_Rn_HORZ</a> (n = 2) <a href="#">HIST_Rn_VERT</a> (n = 2) <a href="#">HIST_Rn_HORZ</a> (n = 3) <a href="#">HIST_Rn_VERT</a> (n = 3)

### 12.5.9.2 Enable/Disable Hardware

Setting the [HIST\\_PCR](#) [0] ENABLE bit enables the histogram module. This must be done after all required registers are programmed and the output memory has been cleared.

When the input source is the memory, the histogram module always operates in one-shot mode. In other words, after enabling the histogram, the ENABLE bit is automatically turned off (set to 0) and only a single frame is processed from memory. In this mode, fetching and processing of the frame begin immediately on setting the ENABLE bit.

When the input source is the CCD, the histogram always operates in continuous mode. Processing of the frame depends on the timing of the CCD. To ensure that data from the CCD is not missed, the histogram must be enabled before CCD so it waits for CCD data.

When the histogram is in continuous mode, it can be disabled by clearing the ENABLE bit during the processing of the last frame. The disable is latched in at the end of the frame in which it is written.

### 12.5.9.3 Event and Status Checking

The histogram generates an interrupt at the end of each frame.

The status of this interrupt can be checked by reading the [ISP\\_IRQ0STATUS](#) register (or [ISP\\_IRQ1STATUS](#)). When the read of the register [ISP\\_IRQ0STATUS](#) occurs (or [ISP\\_IRQ1STATUS](#)), the register is not automatically reset. To reset the interrupt, a 1 must be written to the HIST\_DONE\_IRQ bit.

Each event that generates an interrupt can be individually mapped to ARM or DSP using the [ISP\\_IRQ0ENABLE](#) register (or [ISP\\_IRQ1ENABLE](#)). When a particular event is not enabled (for example [ISP\\_IRQ0ENABLE](#)[x] = 0), the corresponding status ([ISP\\_IRQ0STATUS](#) [x] = 1) bit is flagged if the corresponding event occurs. This has no effect on the interrupt line, but can be used by software to poll the status.

The [HIST\\_PCR](#) [1] BUSY status bit is set when the start of frame occurs (if the [HIST\\_PCR](#) [0] ENABLE bit is 1 at that time). It is automatically reset to 0 at the end of a frame. The [HIST\\_PCR](#) [1] BUSY status bit may be polled to determine the end-of-frame status.

### 12.5.9.4 Register Accessibility During Frame Processing

There are two types of register access in the histogram module.

- **Shadow registers:** These registers/fields can be read and written (if the field is writable) at any time. However, the written values take effect only at the start of a frame. Reads return the most recent write, even though the settings are not used until the next start of frame.

The shadowed registers are:

- HIST\_PCR
- HIST\_RADD
- HIST\_RADD\_OFF
- Busy-lock registers
  - All registers EXCEPT the shadowed registers belong to this category.
  - Busy-lock registers cannot be written when the module is busy. Writes are allowed, but no change occurs in the registers (blocked writes from hardware perspective; allowed write from software perspective).
  - After the HIST\_PCR [1] BUSY bit is reset to 0, the busy-lock registers can be written.
  - The HIST\_DATA register cannot be read when the histogram is busy, because since this register is mapped to memories internally. Such reads return indeterminate data. Byte enables are not implemented for reading the histogram memory.

The ideal procedure for changing the histogram registers is:

```
IF (HIST_PCR [1] BUSY == 0) OR IF (EOF interrupt occurs)
  DISABLE HISTOGRAM
  CHANGE REGISTERS
  ENABLE HISTOGRAM
```

### 12.5.9.5 Interframe Operations

Between frames read from memory, it may be necessary to modify the input memory pointers before processing the next frame. Since the H3A\_PCR and memory pointer registers are shadowed, these modifications can take place any time before the end of the frame, and the data is latched in for the next frame. The MPU Subsystem can perform these changes on receiving an interrupt.

If continuous frames are processed without clearing the histogram output memory, the bin counters contain the counts of however many images are processed since they were last cleared. To read the bin counters for each frame, the bin counters must be read after each frame is completed, but before the next frame begins (since the counters cannot be read while the HIST\_PCR [1] BUSY bit is 1).

If the input source is memory (one-shot mode), the HIST\_PCR [0] ENABLE bit must be set once for the frame, and after the frame is completed, the bin counters can be read/cleared before enabling the next frame.

When the input source is the video-port interface of the CCD (continuous mode), the HIST\_PCR [0] ENABLE bit must be set to enable processing of the frame, and cleared after the frame processing begins (the disable is latched in at the end of the frame). This procedure allows only one frame to be processed. After the frame is completed, the bin counters can be read/cleared before enabling the histogram for the next frame.

### 12.5.9.6 Summary of Constraints

The following is a list of register configuration constraints to adhere to when programming the histogram. It can be used as a quick checklist. More detailed register setting constraints can be found in the individual register descriptions.

- The input address and line offset must be on 32-byte boundaries.
- A region dimension of 1 (horizontal or vertical or both) is not allowed.

### 12.5.10 Programming the Central-Resource SBL

This section discusses issues related to the software control of the central-resource SBL. It lists which registers are required to be programmed in different modes, describes how to check the status of the central resource SBL overflow bits, and enumerates programming constraints.

The central-resource SBL controls data interactions between the camera ISP modules and the interface to memory. A small number of registers configure maximum data-read bandwidth in memory-to-memory operations.

### 12.5.10.1 Hardware Setup/Initialization

This section discusses the configuration of the central-resource SBL required before image processing can begin.

#### 12.5.10.1.1 Reset Behavior

On hardware reset of the camera ISP, all registers in the SBL are reset to their reset values.

#### 12.5.10.1.2 Register Setup

Before enabling any of the camera ISP modules, the hardware must be correctly configured through register writes to the camera ISP registers. If the preview engine, resizer, or the histogram is reading from memory, the [SBL\\_SDR\\_REQ\\_EXP](#) register must be programmed. The values programmed in each of the three fields (PRV\_EXP, RSZ\_EXP, HIST\_EXP) determines the number of clock cycles required to allow two consecutive read requests from the module.

### 12.5.10.2 Enable/Disable Hardware

The central-resource SBL functionality is always enabled, unless the PRCM idles the clocks to the camera ISP.

### 12.5.10.3 Event and Status Checking

The SBL generates one interrupt for the write buffer overflow events listed below. Software must check which overflow event has raised the interrupt request, by reading the [SBL\\_PCR](#) register.

See [Table 12-66](#).

**Table 12-66. SBL Write-Buffer Overflow Events**

Bit	Event Description
<a href="#">SBL_PCR</a> [26] CSIB_WBL_OVF	CSIB write-buffer memory overflow
<a href="#">SBL_PCR</a> [25] CSIA_WBL_OVF	CSIA write-buffer memory overflow
<a href="#">SBL_PCR</a> [24] CCDCPRV_2_RSZ_OVF	CCDC/PREVIEW to RESIZER input overflow This bit is set if the RESIZER input source is sent to CCDC/PREVIEW engine when the active data (to be resized) has already showed up at the resizer interface. In such a case, resizing for this frame cannot take place and the bit is set. This scenario can happen when a resize of 4x is required per frame. Therefore, the RESIZER must operate in two passes. In the first pass, the input data from CCDC/PREVIEW is directly resized and written to memory. In the second pass, the resized data from the first pass is resized again. The next frame from the CCDC/PREVIEW engine should start only after the second pass on the previous frame is complete. This bit indicates the failure status.
<a href="#">SBL_PCR</a> [23] CCDC_WBL_OVF	CCDC write-buffer memory overflow
<a href="#">SBL_PCR</a> [22] PRV_WBL_OVF	PREVIEW write-buffer memory overflow
<a href="#">SBL_PCR</a> [21] RSZ1_WBL_OVF	RESIZER line 1 write-buffer memory overflow
<a href="#">SBL_PCR</a> [20] RSZ2_WBL_OVF	RESIZER line 2 write-buffer memory overflow
<a href="#">SBL_PCR</a> [19] RSZ3_WBL_OVF	RESIZER line 3 write-buffer memory overflow
<a href="#">SBL_PCR</a> [18] RSZ4_WBL_OVF	RESIZER line 4 write-buffer memory overflow
<a href="#">SBL_PCR</a> [17] H3A_AF_WBL_OVF	H3A AF write-buffer memory overflow
<a href="#">SBL_PCR</a> [16] H3A_AEAWB_WBL_OVF	H3A AE/AWB write-buffer memory overflow

The status of this interrupt can be checked by reading the [ISP\\_IRQ0STATUS](#) register (or [ISP\\_IRQ1STATUS](#)). When the read of the register [ISP\\_IRQ0STATUS](#) occurs (or [ISP\\_IRQ1STATUS](#)), the register is not automatically reset. To reset the interrupt, a 1 must be written:

- To the corresponding bit(s) in the [SBL\\_PCR](#) registers
- To the OVF\_IRQ bit in the [ISP\\_IRQ0STATUS](#) register (or [ISP\\_IRQ1STATUS](#))

Each event that generates an interrupt can be individually mapped to ARM or DSP using the [ISP\\_IRQ0ENABLE](#) register (or [ISP\\_IRQ1ENABLE](#)). When a particular event is not enabled (for example [ISP\\_IRQ0ENABLE\[x\] = 0](#)), the correspondent status ([ISP\\_IRQ0STATUS \[x\] = 1](#)) bit is flagged if the correspondent event occurs. This has no effect on the interrupt line, but can be used by software to poll the status.

The SBL flags no read buffer logic underflow events. These are signaled by the reading module. [Table 12-67](#) lists the read port and corresponding events if they exist.

**Table 12-67. SBL Read-Buffer Underflow Events**

Read port	Description
CCDC faulty pixel	When faulty-pixel correction is used, the pixel frequency is imposed by the camera clock. This imposes read-time constraints to the faulty-pixel table read. When the table read was too slow, the <a href="#">CCDC_FPC [16] FPERR</a> bit is set to 1 and no more faulty pixels are processed for that frame. This error generates an interrupt that can be mapped to DSP or ARM by setting the <a href="#">CCDC_ERR_IRQ</a> bit in the <a href="#">ISP_IRQ0ENABLE</a> register (or <a href="#">ISP_IRQ1ENABLE</a> ). To clear this interrupt, clear the <a href="#">CCDC_FPC [16] FPERR</a> bit before clearing the <a href="#">ISP_IRQ0STATUS [11] CCDC_ERR_IRQ</a> bit (or <a href="#">ISP_IRQ1STATUS</a> ).
CCDC lens-shading compensation	There must be adequate memory bandwidth if this feature is enabled. If the data fetched from memory arrives late, then the <a href="#">CCDC_LSC_PREFETCH_ERROR</a> event is triggered and an interrupt generated.
Preview dark frame	There must be adequate memory bandwidth if this feature is enabled. If the data fetched from memory arrives late, the <a href="#">PRV_PCR [31] DRK_FAIL</a> status bit is set to indicate a fail. No interrupt is generated by this event.
Preview image from memory	No error can occur on this port because the preview module stops processing when no image data is ready.
Resizer image from memory	No error can occur on this port because the resizer module stops processing when no image data is ready.
Histogram image from memory	No error can occur on this port because the histogram module stops processing when no image data is ready.
CSI1 image from memory	No error can occur on this port because the CSI1 module stops processing when no image data is ready.

#### 12.5.10.4 Register Accessibility During Frame Processing

The central resource SBL registers are all busy-writable registers.

- Busy-writable registers
  - These registers/fields can be read or written even if the module is busy. Changes to the underlying settings occur instantaneously.

#### 12.5.10.5 Camera ISP Bandwidth Adjustments

For memory-to-memory operation, the camera ISP processes data at the highest possible data rate. If this processing returns results long before real-time deadlines, the performance of other peripherals in the system may be negatively affected. The camera ISP offers two kinds of adjustments that can slow down data processing in this situation. One can be made when the sensor input to the CCDC is the input source, and the other can be made when the memory is the source of the input image.

### 12.5.10.5.1 Input From CCDC Video-Port Interface

The video-port interface delivers data at a rate independent of the pixel clock when the data reformatter is enabled. By default, this rate is set to 83 MHz, which is fast enough to support a parallel interface clock of 75 MHz or a CSI clock of 83 MHz. When the pixel clock is at a lower frequency, it is unnecessary for the video-port interface to operate at such a high frequency. The `CCDC_FMTCFG` [18:16] `VPIF_FRQ` field of the CCDC can be programmed to reduce the rate at which the video port delivers new data to the other modules (Preview, H3A, and histogram). In effect, this register indirectly controls the output bandwidth of the preview engine, resizer, and H3A. Depending on the input sensor clock, Users can set this field appropriately and balance the bandwidth requirements to memory. [Figure 12-112](#) demonstrates how this register can expand processing time per line for lower PCLK frequencies.

**Figure 12-112. Video-Port Interface Bandwidth Balancing**

camisp-091

### 12.5.10.5.2 Input From Memory

When the input image is from memory, data is fetched from memory and processed at a steady state rate of 166 MB/sec. Depending on the image size and real-time deadline for each frame, this may be much faster than necessary. Such activity can also starve other processes in the system. Internally, when a CAMERA ISP module receives input from memory, the CAMERA ISP makes a read request to the L3 interconnect whenever there is available memory in its internal buffers.

The `SBL_SDR_REQ_EXP` register can be programmed to control the rate at which a camera ISP module (Preview, resizer, or histogram) reads the input frame from memory. This indirectly controls the output bandwidth of the preview engine and resizer. Depending on the size of the images and the real-time deadlines, users can set this field appropriately and balance the bandwidth requirements to memory.

The minimum number of cycles (L3) in between read requests used to program the `SBL_SDR_REQ_EXP` register can be determined based on the frame size and real-time requirement using the following equation:

$$\text{Number of cycles/request} = (\text{DMA cycles/frame}) / (\text{DMA read requests/frame})$$

In the previous equation, (DMA cycles/frame) is based on a real-time requirement. For example, if the real-time requirement is a frame rate of 1/30 sec and the L3 clock is 166 MHz, this can be calculated as:

$$(\text{DMA cycles/frame}) = \text{L3 clock} * \text{frame rate} = 166 \text{ MHz} * 1/30 = 5.53\text{M cycles}$$

The (DMA read requests/frame) is based on the frame size and the alignment in memory. Assuming a VGA (640 x 480) frame size and optimal alignment conditions:

$$(\text{DMA read requests/frame}) = \text{Transfers per line} * \text{number of lines} = 640 \text{ pix/line} * 2 \text{ bytes/pix} / 256 \text{ bytes/xfer} * 480 \text{ lines} = 2400 \text{ requests/frame}$$

In this example, the final equation can now be solved:

$$\text{Number of cycles/request} = 5.53\text{M cyles} / 2400 \text{ requests} = 2306 \text{ cycles/request}$$

[Figure 12-113](#) demonstrates how this register can expand processing time for lower real-time requirements.

**Figure 12-113. Memory Read Bandwidth Balancing**

The maximum values that can be written to the [SBL\\_SDR\\_REQ\\_EXP](#) register for the different read requestors is 1023. For the histogram and preview engine, this should be sufficient for the typical size of RAW data frames. However, because the resizer can read a variety of video frame sizes, the field for the resizer is internally multiplied by 1024. Therefore, for this example, the [SBL\\_SDR\\_REQ\\_EXP\[19:10\]](#) RSZ\_EXP bit field can be programmed to  $FLOOR(2306/1024) = 2$ .

The previous equations provide an estimate or a starting point for programming this register. Depending on the system loads and available bandwidth, it may be necessary to reduce this number to compensate for a heavily loaded system.

---

**NOTE:** The granularity for the resizer is 1024, and for the preview and HIST it is 32.

---

## 12.5.11 Programming the Circular Buffer (CBUFF)

### 12.5.11.1 Hardware Setup/Initialization

This section discusses the configuration of the circular buffer required before address translation can begin.

### 12.5.11.2 Reset Behavior

Upon hardware reset of the circular buffer, all of the registers in the circular buffer are reset to their reset values.

### 12.5.11.3 Register Setup

All registers of the circular buffer to be used (CBUFFx, x=0 or 1) have to be initialized for correct operation.

The [CBUFFx\\_START](#) and [CBUFFx\\_END](#) register define the virtual address range managed by the circular buffer. It usually corresponds to the address region where one image frame is written by the camera ISP.

The window count and size are set through the [CBUFFx\\_CTRL \[9:8\]](#) WCOUNT and [CBUFFx\\_WINDOWSIZE](#) registers. The window size usually depends on the utilization of the buffer. 8 or 16 video lines correspond to a current size for JPEG video compression. A higher window count provides better latency related overflow protection.

When the camera ISP accesses data in an incremental addressing scheme, the next window is never used. In this case the overflow event generation, when the processor window falls into the "next window", can be disabled by setting the [CBUFFx\\_CTRL \[3\]](#) ALLOW\_NW\_EQ\_CPUW flag.

When the 2D addressing capability isn't used the [CBUFFx\\_THRESHOLD](#) register is set to the window size. Otherwise it is set to a smaller value depending on the buffer organization. For example, when each window corresponds to 8 lines by 4096 pixel but the camera ISP only send lines of 2560 pixels the [CBUFFx\\_WINDOWSIZE](#)=8\*4096 and [CBUFFx\\_THRESHOLD](#)=8\*2560.

When the register setup is completed the module is enabled using the [CBUFFx\\_CTRL](#) [0] EN bit.

It can be disabled by clearing the [CBUFFx\\_CTRL](#) [0] EN bit. This must only be done when there are no more outstanding requests to the virtual space managed by CBUFFx. All internal FSMs and counters of the circular buffer are reset when it is disabled. Pending interrupts are not affected.

## 12.5.11.4 Event and status Checking

### 12.5.11.4.1 Interrupts

All events generated by the circular buffer are mapped to an unique event at camera ISP level: [CBUFF\\_IRQ](#),

The CBUFF module event can be mapped to the MPU SS or to the IVA SS.

The [CBUFF\\_IRQ](#) bit in the [ISP\\_IRQ0ENABLE](#) [21] [CBUFF\\_IRQ](#) register control whether the CBUFF module event triggers an interrupt to the MPU SS. The [CBUFF\\_IRQ](#) bit in the [ISP\\_IRQ0ENABLE](#) [21] [CBUFF\\_IRQ](#) register control whether the CBUFF module event triggers an interrupt to the IVA2.2 SS.

When an event has been triggered the [ISP\\_IRQ0STATUS](#) [21] [CBUFF\\_IRQ](#) bit is set (or [ISP\\_IRQ1STATUS](#)). SW must than read the [CBUFF\\_IRQSTATUS](#) register to know which circular buffer event has triggered the interrupt. SW must clear the event first in the circular buffer module by writing 1 to the proper bit in [CBUFF\\_IRQSTATUS](#) register and then clear the event at camera ISP level by writing 1 to the [ISP\\_IRQ0STATUS](#) [21] [CBUFF\\_IRQ](#) bit (or [ISP\\_IRQ1STATUS](#)). If another event is pending at circular buffer level, the [CBUFF\\_IRQ](#) interrupt is triggered again.

### 12.5.11.4.2 Status Checking

The event status can be checked through the [CBUFFx\\_READY\\_IRQ](#), [CBUFFx\\_INVALID\\_IRQ](#) and [CBUFFx\\_OVR\\_IRQ](#) bits in the [CBUFF\\_IRQSTATUS](#) registers.

In addition to those status bits the circular buffer module provides read only access to the "current window", "next window" and "CPU windows" indexes through the [CBUFFx\\_STATUS](#) register. The "CPU window" index can for example be used by the processor to compute the address of the physical buffer. Those indexes can also be used to evaluate latency margins.

## 12.5.11.5 Register Accessibility During Frame Processing

All registers are Busy-writeable registers. These registers/fields can be read or written even if the module is busy. Changes to the underlying settings takes place instantaneously. However the module behavior is unpredictable when registers are changed during processing.

For correct operation software must follow the following steps:

- Disable all accesses to the virtual space managed by CBUFFx. For example when the circular buffer relocates data provided by the CCDC module SW must disable the CCDC module and check SBL status registers to make sure there are no more outstanding transactions.
- Disable circular buffer x by clearing the [CBUFFx\\_CTRL](#) [0] ENABLE bit.
- Change the configuration.
- Re-enable CBUFFx by setting the [CBUFFx\\_CTRL](#) [0] ENABLE bit.

## 12.5.11.6 Operations

A [CBUFFx\\_READY\\_IRQ](#) event is generated each time processor can read data from the circular buffer. Processor can clear the event when it starts processing the data to avoid masking of other events. Processor can keep trace of the location on the data internally or use the circular buffer registers to compute it.

The formula used is:

$$\text{ADDR} = \text{CBUFF}_x\text{\_STATUS} [3:0] \text{ CPUW} \times \text{CBUFF}_x\text{\_WINDOWSIZE} + \text{CBUFF}_x\text{\_START} \quad (6)$$

When processor is done with processing, it must free the buffer by setting the [CBUFF<sub>x</sub>\\_CTRL \[2\] DONE](#) bit. Otherwise an overflow event may occur.

Note that the circular buffer does not keep trace of end of frame events. They have to be managed by the processor using the end of frame event of the module that writes into the circular buffer. At the end of the frame there may remain data in the "current write" and "next write" windows. For example, when the window size is set to 8 lines and the image size is 20 lines only 2 window ready events are generated for a linear addressing scheme. The remaining 4 lines can be read after the end of frame event.

No automatic reset of the CBUFF FSM occurs at the end of the camera ISP frame. Software must reset the CBUFF by clearing the [CBUFF<sub>x</sub>\\_CTRL \[0\] ENABLE](#) bit when the frame has been completely processed. A new frame can only start when [CBUFF<sub>x</sub>\\_CTRL \[0\] ENABLE](#) has been set.

## 12.6 Camera ISP Register Manual

### 12.6.1 Camera ISP Instance Summary

**Table 12-68. Camera ISP Instance Summary**

Module Name	Base Address (hex)	Size
ISP	0x480B C000	256 bytes
ISP_CBUFF	0x480B C100	256 bytes
ISP_CSI1B	0x480B C400	512 bytes
ISP_CCDC	0x480B C600	512 bytes
ISP_HIST	0x480B CA00	512 bytes
ISP_H3A	0x480B CC00	512 bytes
ISP_PREVIEW	0x480B CE00	512 bytes
ISP_RESIZER	0x480B D000	512 bytes
ISP_SBL	0x480B D200	512 bytes

Bits	Field Name	Description	Type	Reset
31	HS_VS_IRQ	HS or VS synchro event This event is triggered if a rising or falling edge is detected on the HS or VS signal. The rising or falling edge and the HS or VS signal selection is chosen with the <a href="#">ISP_CTRL.SYNC_DTECT</a> bit field. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
30	RESERVED	RESERVED	RW	0x0
29	OCP_ERR_IRQ	ISP Interconnect error. This event is triggered when an Interconnect error occurs: SResp = ERR. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
28	MMU_ERR_IRQ	MMU error. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
27:26	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
25	OVF_IRQ	Central Resource SBL overflow This event is triggered when one of the buffer in the central resource SBL overflows. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
24	RSZ_DONE_IRQ	RESIZER module - resizer processing done event. This event is triggered at the end of the frame when the processing is completed for the current frame. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
23:22	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0

Bits	Field Name	Description	Type	Reset
21	CBUFF_IRQ	Circular buffer interrupt 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
20	PRV_DONE_IRQ	PREVIEW module - processing done event. This event is triggered at the end of the frame when the processing is completed for the current frame. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
19	CCDC_LSC_PREFETCH_ERROR	The prefetch error indicates when the gain table was read to slowly from SDRAM. When this event is pending the module goes into transparent mode (output=input). Normal operation can be resumed at the start of the next frame after 1) clearing this event 2) disabling the LSC module 3) enabling it 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
18	CCDC_LSC_PREFETCH_COMPLETED	Indicates current state of the prefetch buffer. Can be used to start sending the data once the buffer is full to minimize the risk of an underflow. This event is triggered when the buffer contains 3 full paxel rows. It can be used to minimize buffer underflow risks. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
17	CCDC_LSC_DONE	The event is triggered when the internal state of LSC toggles from BUSY to IDLE. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
16	HIST_DONE_IRQ	HIST module - processing done event. This event is triggered at the end of the frame when the processing is completed for the current frame. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
15:14	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
13	H3A_AWB_DONE_IRQ	H3A module - auto exposure and auto white balance processing done event. This event is triggered at the end of the frame when the processing is completed for the current frame. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
12	H3A_AF_DONE_IRQ	H3A module - autofocus processing done event. This event is triggered at the end of the frame when the processing is completed for the current frame. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
11	CCDC_ERR_IRQ	CCDC module - faulty pixel correction memory underflow 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
10	CCDC_VD2_IRQ	CCDC module - programmable event 2 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
9	CCDC_VD1_IRQ	CCDC module - programmable event 1. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0

Bits	Field Name	Description	Type	Reset
8	CCDC_VD0_IRQ	CCDC module - programmable event 0. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
7	CSIB_LC3_IRQ	CSI1 receiver module - event on logical channel 3. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
6	CSIB_LC2_IRQ	CSI1 receiver module - event on logical channel 2 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
5	CSIB_LC1_IRQ	CSI1 receiver module - event on logical channel 1 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
4	CSIB_LC0_IRQ	CSI1 receiver module - event on logical channel 0 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
3	CSIB_LCM_IRQ	CSI1 RECEIVER module - event on memory channel. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0
2	RESERVED	Reserved bit field. Write the reset value.	RW	0x0
1	RESERVED	Reserved bit field. Write the reset value.	RW	0x0
0	CSIA_IRQ	CSIA_RECEIVER module event. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0x0

**Table 12-82. ISP\_IRQ1STATUS**

<b>Address Offset</b>	0x0000 0018	
<b>Physical Address</b>	0x480B C018	<b>Instance</b> ISP
<b>Description</b>	INTERRUPT STATUS REGISTER TO DSP. IRQ1 STATUS LINE.	
<b>Type</b>	RW	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
HS_VS_IRQ	RESERVED	OCF_ERR_IRQ	MMU_ERR_IRQ	RESERVED	OVF_IRQ	RSZ_DONE_IRQ	RESERVED	CBUFF_IRQ	PRV_DONE_IRQ	CCDC_LSC_PREFETCH_ERROR	CCDC_LSC_PREFETCH_COMPLETED	CCDC_LSC_DONE	HIST_DONE_IRQ	RESERVED	H3A_AWB_DONE_IRQ	H3A_AF_DONE_IRQ	CCDC_ERR_IRQ	CCDC_VD2_IRQ	CCDC_VD1_IRQ	CCDC_VD0_IRQ	CSIB_LC3_IRQ	CSIB_LC2_IRQ	CSIB_LC1_IRQ	CSIB_LC0_IRQ	CSIB_LCM_IRQ	RESERVED	RESERVED	RESERVED	RESERVED	CSIA_IRQ	

Bits	Field Name	Description	Type	Reset
31	HS_VS_IRQ	HS or VS synchro event <sup>(1)</sup> READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
30	RESERVED	RESERVED	R/W	0x0

<sup>(1)</sup> This event is detected on the incoming HS/VS signals before the CCDC. Therefore, it cannot be used in BT656 mode.

Bits	Field Name	Description	Type	Reset
29	OCP_ERR_IRQ	ISP Interconnect error. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
28	MMU_ERR_IRQ	MMU error. If event is true, one needs to read the MMU_IRQSTATUS register to know the event source. Write in MMU_IRQSTATUS to clear the bit. READS: 0: event is false 1: event is true	R/W/1to Clr	0x0
27:26	RESERVED	Write 0s for future compatibility. Reads returns 0.	R/W/1to Clr	0x0
25	OVF_IRQ	Central Resource SBL overflow If event is true, one needs to check the <a href="#">SBL_PCR</a> register to know the source. One needs to clear the <a href="#">SBL_PCR</a> register first before clearing this bit. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
24	RSZ_DONE_IRQ	RESIZER module - resizer processing done event. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset  0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	R/W/1to Clr	0x0
23:22	RESERVED	Write 0s for future compatibility. Reads returns 0.	R/W/1to Clr	0x0
21	CBUFF_IRQ	A circular buffer event is pending. Check submodule's interrupt status register. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
20	PRV_DONE_IRQ	PREVIEW module - processing done event. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
19	CCDC_LSC_PREFETCH_ERROR	The prefetch error indicates when the gain table was read to slowly from SDRAM. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0

Bits	Field Name	Description	Type	Reset
18	CCDC_LSC_PREFETCH_COMPLETED	Indicates current state of the prefetch buffer. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
17	CCDC_LSC_DONE	The event is triggered when the internal state of LSC toggles from BUSY to IDLE. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
16	HIST_DONE_IRQ	HIST module - processing done event. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
15:14	RESERVED	Write 0s for future compatibility. Reads returns 0.	R/W/1to Clr	0x0
13	H3A_AWB_DONE_IRQ	H3A module - auto exposure and auto white balance processing done event. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
12	H3A_AF_DONE_IRQ	H3A module - autofocus processing done event. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
11	CCDC_ERR_IRQ	CCDC module - faulty pixel correction memory underflow If event is true, one needs to clear the <a href="#">CCDC_FPC.FPERR</a> bit first before clearing this bit. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
10	CCDC_VD2_IRQ	CCDC module - programmable event 2 READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
9	CCDC_VD1_IRQ	CCDC module - programmable event 1. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0

Bits	Field Name	Description	Type	Reset
8	CCDC_VDO_IRQ	CCDC module - programmable event 0. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
7	CSIB_LC3_IRQ	CSI1 receiver module - event on logical channel 3. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
6	CSIB_LC2_IRQ	CSI1 receiver module - event on logical channel 2 . READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
5	CSIB_LC1_IRQ	CSI1 receiver module - event on logical channel 1. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
4	CSIB_LC0_IRQ	CSI1 receiver module - event on logical channel 0. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
3	CSIB_LCM_IRQ	CSI1/CCP2B receiver module - event on memory channel. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0
2	RESERVED	Reserved bit field. Write the reset value.	R/W/1to Clr	0x0
1	RESERVED	Reserved bit field. Write the reset value.	R/W/1to Clr	0x0
0	CSIA_IRQ	CSIA RECEIVER module event. If event is true, one needs to read the CSIA_IRQSTATUS register to know the event source. Write in CSIA_IRQSTATUS to clear the bit. READS: 0: event is false 1: event is true WRITES 0: status bit unchanged 1: status bit reset	R/W/1to Clr	0x0

**Table 12-84. TCTRL\_GRESET\_LENGTH**

<b>Address Offset</b>	0x0000 0030	
<b>Physical Address</b>	0x480B C030	<b>Instance</b> ISP
<b>Description</b>	TIMING CONTROL - GLOBAL SHUTTER LENGTH REGISTER This register is used by the TIMING CTRL module to generate the cam_global_reset signal.	
<b>Type</b>	RW	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								LENGTH																							

Bits	Field Name	Description	Type	Reset
31:24	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x00
23:0	LENGTH	Sets the length of the cam_global_reset signal assertion in cycles of the CNTCLK clock. The CNTCLK frequency is generated with the TCTRL_CTRL.DIVC bit field. After signal assertion, the TCTRL_CTRL.GRESETEN bit is automatically cleared. The possible values are 0 to 2 <sup>24</sup> -1 cycles. The polarity of the cam_global_reset signal is set by the TCTRL_CTRL.GRESETPOL bit.	RW	0x000000

**Table 12-85. Register Call Summary for Register TCTRL\_GRESET\_LENGTH**

**Table 12-86. TCTRL\_PSTRB\_REPLAY**

<b>Address Offset</b>	0x0000 0034	
<b>Physical Address</b>	0x480B C034	<b>Instance</b> ISP
<b>Description</b>	TIMING CONTROL - PRESTROBE REPLAY REGISTER This register is used by the TIMING CTRL module to generate the prestrobe signal.	
<b>Type</b>	RW	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
COUNTER								DELAY																							

Bits	Field Name	Description	Type	Reset
31:25	COUNTER	Sets the number of PRESTROBE pulses after the original pulse. If this bit is set to 0, the PRESTROBE signal behavior is only controlled by <a href="#">TCTRL_FRAME.STRB</a> , <a href="#">TCTRL_PSTRB_DELAY</a> and <a href="#">TCTRL_PSTRB_LENGTH</a> . If <a href="#">TCTRL_PSTRB_LENGTH</a> =0, there is no replay. This bit is useful when one wants to enable red-eye removal.	RW	0x00
24:0	DELAY	Sets the delay for the PRESTROBE signal re-assertion in cycles of the CNTCLK clock. The CNTCLK frequency is generated with the <a href="#">TCTRL_CTRL.DIVC</a> bit field. The possible values are 0 to $2^{25}-1$ cycles. If <a href="#">TCTRL_PSTRB_LENGTH</a> =0, there is no replay. This bit field must not be set to 0 if the COUNTER is set to a value different of 0. This bit is useful when one wants to enable red-eye removal.	RW	0x0000000

**Table 12-88. ISP\_CTRL**

<b>Address Offset</b>	0x0000 0040	<b>Instance</b>	ISP
<b>Physical Address</b>	<a href="#">0x480B C040</a>		
<b>Description</b>	CONTROL REGISTER After reset, the parallel interface is selected and only the CCDC module data write port is enabled.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FLUSH	JPEG_FLUSH	CCDC_WEN_POL	SBL_SHARED_RPORTB	SBL_SHARED_RPORTA	RESERVED	CBUFF1_BCF_CTRL	CBUFF0_BCF_CTRL	SBL_AUTOIDLE	SBL_WR0_RAM_EN	SBL_WR1_RAM_EN	SBL_RD_RAM_EN	PREV_RAM_EN	CCDC_RAM_EN	SYNC_DETECT	RSZ_CLK_EN	PRV_CLK_EN	HIST_CLK_EN	H3A_CLK_EN	CBUFF_AUTOGATING	CCDC_CLK_EN	SHIFT	RESERVED	PAR_CLK_POL	PAR_BRIDGE	PAR_SER_CLK_SEL						

Bits	Field Name	Description	Type	Reset
31	FLUSH	CCDC memory flush Writing 1 in this bit flushes the CCDC memories in the central resource SBL. The SBL memories are always flushed by the end of frame. However, there are cases where the end of frame cannot be detected.	RW	0x0
30	JPEG_FLUSH	JPEG flush When a camera module outputs a JPEG bit stream, this bit must be set because the bit stream length may not be a multiple of 32 bits. Enabling this bit ensures that no data stay in the design internal FIFOs.	RW	0x0
29	CCDC_WEN_POL	Sets the polarity of the CCDC WEN bit. 0x0: Active low 0x1: Active high	RW	0x0

Bits	Field Name	Description	Type	Reset
28	SBL_SHARED_RPORTB	Controls SBL shared read port B access 0x0: Read port used by preview module dark frame read 0x1: Read port used by CCDC module lens-shading compensation data read	RW	0x0
27	SBL_SHARED_RPORTA	Controls SBL shared read port A access 0x0: Read port used by preview module data read 0x1: Read port used by CSI1 module data read	RW	0x0
26	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
25:24	CBUFF1_BCF_CTRL	Bandwidth control feedback loop configuration register 0x0: Disabled. 0x1: The BCF signal of CBUFF1 stalls the response phase of the CS1b OCP read master port. 0x2: The BCF signal of CBUFF1 stalls the request phase of the CS1b OCP read master port. 0x3: The BCF signal of CBUFF1 stalls the request and response phase of the CS1b OCP read master port.	RW	0x0
23:22	CBUFF0_BCF_CTRL	Bandwidth control feedback loop configuration register 0x0: Disabled. 0x1: The BCF signal of CBUFF0 stalls the response phase of the CS1b OCP read master port. 0x2: The BCF signal of CBUFF0 stalls the request phase of the CS1b OCP read master port. 0x3: The BCF signal of CBUFF0 stalls the request and response phase of the CS1b OCP read master port.	RW	0x0
21	SBL_AUTOIDLE	Sets the SBL autoidle mode 0x0: Disabled 0x1: Enabled	RW	0x1
20	SBL_WR0_RAM_EN	This bit controls the SBL module WRITE0 RAM used by the RESIZER module. If the RESIZER module is disabled, this bit should be set to 0 to save power. 0x0: RAM is disabled 0x1: RAM is enabled	RW	0x0
19	SBL_WR1_RAM_EN	This bit controls the SBL module WRITE1 RAM. If the RESIZER module is the only module enabled to perform memory to memory resize operations, this bit should be set to 0 to save power. 0x0: RAM is disabled 0x1: RAM is enabled	RW	0x0
18	SBL_RD_RAM_EN	This bit controls the SBL module READ RAM. If no read requests are generated, this bit should be set to 0 to save power. 0x0: RAM is disabled 0x1: RAM is enabled	RW	0x0
17	PREV_RAM_EN	This bit controls the PREVIEW module RAM. If the PREVIEW module is not used, this bit should be set to 0 to save power. 0x0: RAM is disabled 0x1: RAM is enabled	RW	0x0
16	CCDC_RAM_EN	This bit controls the CCDC module RAM. If the CCDC module is not used, the bit should be set to 0 to save power. 0x0: RAM is disabled 0x1: RAM is enabled	RW	0x0

Bits	Field Name	Description	Type	Reset
15:14	SYNC_DETECT	<p>HS or VS synchronization signal detection It is sometimes necessary to detect the rising or falling edge of the horizontal and vertical synchro signals. When such event is detected, an interrupt is triggered if <a href="#">ISP_IRQ0ENABLE.HS_VS_IRQ</a> = 1 or <a href="#">ISP_IRQ0ENABLE.HS_VS_IRQ</a> = 1.</p> <p>0x0: HS falling edge 0x1: HS rising edge 0x2: VS falling edge 0x3: VS rising edge</p>	RW	0x0
13	RSZ_CLK_EN	<p>RSZ module clock enable. This bit controls the clock distribution to the RSZ module.</p> <p>0x0: Disable clock. The module is not active. However, accesses on the module slave port to configure it are still possible. 0x1: Enable clock. The module is fully functional.</p>	RW	0x0
12	PRV_CLK_EN	<p>PRV module clock enable. This bit controls the clock distribution to the PRV module.</p> <p>0x0: Disable clock. The module is not active. However, accesses on the module slave port to configure it are still possible. 0x1: Enable clock. The module is fully functional.</p>	RW	0x0
11	HIST_CLK_EN	<p>HIST module clock enable. This bit controls the clock distribution to the HIST module.</p> <p>0x0: Disable clock. The module is not active. However, accesses on the module slave port to configure it are still possible. 0x1: Enable clock. The module is fully functional.</p>	RW	0x0
10	H3A_CLK_EN	<p>H3A module clock enable. This bit controls the clock distribution to the H3A module.</p> <p>0x0: Disable clock. The module is not active. However, accesses on the module slave port to configure it are still possible. 0x1: Enable clock. The module is fully functional.</p>	RW	0x0
9	CBUFF_AUTOGATING	<p>CBUFF module autogating feature control</p> <p>0x0: CBUFF autogating feature is disabled. The CBUFF internal clock is free running. 0x1: CBUFF autogating feature is enabled. The CBUFF internal clock is only enabled when it is requested by the CBUFF module.</p>	RW	0x1
8	CCDC_CLK_EN	<p>CCDC module clock enable. This bit controls the clock distribution to the CCDC module.</p> <p>0x0: Disable clock. The module is not active. However, accesses on the module slave port to configure it are still possible. 0x1: Enable clock. The module is fully functional.</p>	RW	0x0

Bits	Field Name	Description	Type	Reset
7:6	SHIFT	<p>Data lane shifter</p> <p>The parallel interface is a 12-bit interface, The video port of CSI1 is a 12-bit interface, The video port of CSI2 is a 14-bit interface. The Camera ISP has 14 data lanes but the full imaging pipeline only supports 10 bits. There are 2 main utilizations of the data lane shifter</p> <p>1) Dynamic reduction: For example data from a 12 bit sensor can be converted into 10bit. 2) When a camera module as fewer than 12 data lanes, the ISP requires the pins to be connected on the least significant lanes. An issue occurs when a n-bit camera parallel interface can work in a m-bit mode with mn. The ISP expects the m bits to be on the least significant data lanes whereas it is not correct. The data lane shifter takes place before the CCDC module</p> <p>0x0: No shift. CAMEXT[13:0] - CAM [13:0] 0x1: Shift by 2. CAMEXT[13:2] - CAM [11:0] 0x2: Shift by 4 CAMEXT[13:4] - CAM [9:0] 0x3: Shift by 6 CAMEXT[13:6] - CAM [7:0]</p>	RW	0x0
5	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
4	PAR_CLK_POL	<p>This bit sets the pixel clock polarity on the parallel interface. The pixel clock is used for latching the pixel data into the CCDC module.</p> <p>0x0: Clock not inverted. The data are sampled on the rising edge of the clock. 0x1: Clock inverted. The data are sampled on the falling edge of the clock.</p>	RW	0x0
3:2	PAR_BRIDGE	<p>This bit field controls the 8 to 16-bit bridge at the input of the CCDC module.</p> <p>0x0: The bridge is disabled: no conversion. 0x1: Reserved 0x2: The bridge is enabled. The first byte is written to cam_d[7:0], the second byte is written to cam_d[15:8] 0x3: The bridge is enabled. The first byte is written to cam_d[15:8], the second byte is written to cam_d[7:0]</p>	RW	0x0
1:0	PAR_SER_CLK_SEL	<p>Selects the serial or parallel interface as the input to the preview hardware.</p> <p>0x0: Selects the 12-bit parallel interface as the input to the CCDC module. 0x1: Selects the CSIA serial interface as the input to the CCDC module. 0x2: Selects the CSIB serial interface as the input to the CCDC module.</p>	RW	0x0

**Table 12-90. TCTRL\_CTRL**

<b>Address Offset</b>	0x0000 0050	<b>Instance</b>	ISP
<b>Physical Address</b>	0x480B C050		
<b>Description</b>	TIMING CONTROL - CONTROL REGISTER		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
GRESETDIR	GRESETPOL	GRESETEN	INSEL	STRBPSTRBPOL	RESERVED	SHUTPOL	STRBEN	PSTRBEN	SHUTEN	RESERVED	DIVC						DIVB			DIVA											

Bits	Field Name	Description	Type	Reset
31	GRESETDIR	Sets the direction of the cam_global_reset signal. 0x0: INPUT. cam_global_reset is an input to the TIMING CONTROL module. cam_global_reset is externally generated. 0x1: OUTPUT. cam_global_reset is an output of the TIMING CONTROL module. cam_global_reset is internally generated. If GRESETEN is set to 1, the internally generated cam_global_reset triggers the generation of the PRESTROBE, STROBE and SHUTTER signals. The frame counters are ignored.	RW	0x0
30	GRESETPOL	Sets the polarity of the global reset signal: cam_global_reset. It applies whatever the direction of the cam_global_reset signal: input or output. 0x0: active high 0x1: active low	RW	0x0

Bits	Field Name	Description	Type	Reset
29	GRESETEN	Triggers the generation of the cam_global_reset signal. The signal is asserted immediately. If enabled, the cam_global_reset signal is asserted for <a href="#">TCTRL_GRESET_LENGTH</a> cycles. After the signal assertion, the enable bit is automatically cleared to 0. The polarity of the cam_global_reset signal is set with <a href="#">TCTRL_CTRL.GRESETPOL</a> . Enabling this bit triggers the generation of the cam_shutter and cam_strobe signals (if previously enabled). The frame counters must be set to 0 when this bit is set to 1 and GRESETDIR is set a OUTPUT.	RW	0x0
28:27	INSEL	Sets the mode that triggers the SHUTTER, PRESTROBE and STROBE signals.  0x0: Video Port. The VS sync pulse at the input of the CCDC module is used to count the frames. The source of the VS pulse is selected by the <a href="#">ISP_CTRL [1:0] PAR_SER_CLK_SEL</a> register.  0x1: CSIA interface. The frame start code (FSC) and frame end code (FEC) sync codes are used to count the frames.  0x2: CSIB interface. The frame start code (FSC) and frame end code (FEC) sync codes are used to count the frames.  0x3: GRESET. The cam_global_reset input signal triggers the SHUTTER, PRESTROBE and STROBE signals. In this mode, there are no frame counters. The delay counters start decrementing as soon as the cam_global_reset signal is asserted. The polarity of the cam_global_reset signal is set with <a href="#">TCTRL_CTRL.GRESETPOL</a> .	RW	0x0
26	STRBPSTRBPOL	Sets the polarity of the strobe and prestrobe signals.  0x0: Active high 0x1: Active low	RW	0x0
25	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
24	SHUTPOL	Sets the polarity of the mechanical shutter signal: cam_shutter  0x0: Active high 0x1: Active low	RW	0x0
23	STRBEN	Flash strobe signal enable. If enabled, the STROBE signal is asserted after <a href="#">TCTRL_FRAME.STRB</a> frames have been received and a delay of <a href="#">TCTRL_STRB_DELAY</a> cycles have passed. The STROBE signal is asserted for <a href="#">TCTRL_STRB_LENGTH</a> cycles. After the signal assertion, the enable bit is automatically cleared to 0. This signal must not be disabled by software.	RW	0x0
22	PSTRBEN	Flash prestrobe signal enable. If enabled, the PRESTROBE signal is asserted after <a href="#">TCTRL_FRAME.PSTRB</a> frames have been received and a delay of <a href="#">TCTRL_PSTRB_DELAY</a> cycles have passed. The PRESTROBE signal is asserted for <a href="#">TCTRL_PSTRB_LENGTH</a> cycles. After the signal assertion, the enable bit is automatically cleared to 0. This signal must not be disabled by software.	RW	0x0
21	SHUTEN	Mechanical shutter signal enable. If enabled, the SHUTTER signal is asserted after <a href="#">TCTRL_FRAME.SHUT</a> frames have been received and a delay of <a href="#">TCTRL_SHUT_DELAY</a> cycles have passed. The SHUTTER signal is asserted for <a href="#">TCTRL_SHUT_LENGTH</a> cycles. After the signal assertion, the enable bit is automatically cleared to 0. This signal must not be disabled by software.	RW	0x0

Bits	Field Name	Description	Type	Reset
20:19	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
18:10	DIVC	Sets the clock divisor value for the CNTCLK clock generation based on the CAM_MCLK input clock. CNTCLK is an internal clock used by the TIMING CTRL module counters. Usually, CNTCLK = CAM_MCLK/DIVC, except for some particular values shown hereafter.  0x0: No clock. CNTCLK is gated.	RW	0x000
9:5	DIVB	Sets the clock divisor value for the cam_xclkb clock generation based on the CAM_MCLK input clock. Usually, cam_xclkb = CAM_MCLK/DIVB, except for some particular values shown hereafter. This bit field is not reset by a soft reset; a hard reset is required. It enables to keep the clock configuration stable through a soft reset.  0x0: cam_xclkb = stable low level. Divider disabled. 0x1: cam_xclkb = stable high level. Divider disabled. 0x1F: cam_xclkb = cam_xclk. Bypass.	RW	0x00
4:0	DIVA	Sets the clock divisor value for the cam_xclka clock generation based on the CAM_MCLK input clock. Usually, cam_xclka = CAM_MCLK/DIVA, except for some particular values shown hereafter. This bit field is not reset by a soft reset; a hard reset is required. It enables to keep the clock configuration stable through a soft reset.  0x0: cam_xclka = stable low level. Divider disabled. 0x1: cam_xclka = stable high level. Divider disabled. 0x1F: cam_xclka = cam_xclk. Bypass.	RW	0x00

**Table 12-117. CBUFFx\_CTRL**

<b>Address Offset</b>	0x0000 0020 + (0x4 * x)	<b>Index</b>	x = 0 to 1
<b>Physical Address</b>	0x480B C120 + (0x4 * x) 0x480B C120 + (0x4 * x)	<b>Instance</b>	ISP ISP_CBUFF
<b>Description</b>	Circular buffer x control register		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																WCOUNT		BCF				ALLOW_NW_EQ_CPUW	DONE	RWMODE	ENABLE						

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x000000
9:8	WCOUNT	Window count 0x0: 2 windows 0x1: 4 windows 0x2: 8 windows 0x3: 16 windows	RW	0x0
7:4	BCF	This register controls the bandwidth control feedback loop output. Functionality depends on subsystem integration. 0: Control loop disabled. Data read from memory is free running. 1-15: The control feedback loop signal is asserted when the window count available for ISP is below ( ) the threshold. In other words at least (=) BCF windows are available for ISP access when this signal is released.	RW	0x0
3	ALLOW_NW_EQ_CPUW	Allow NW=CPUW. Better buffer utilization when ISP does not use the next write window.  0x0: When the CPUW and the NW pointers designate the same window and accesses are effectively performed to those windows an overflow event occurs. This happens when - the CPU has received an READY IRQ for that window indicating that it can be accessed and - the ISP performs an access to that window. ISP accesses are tracked based on OCPI activity.  0x1: When the CPUW and the CW pointers designate the same window and accesses are effectively performed to those windows an overflow event occurs. This happens when - the CPU has received an READY IRQ for that window indicating that it can be accessed and - the ISP performs an access to that window. ISP accesses are tracked based on OCPI activity.	RW	0x0
2	DONE	Write this bit to 1 to indicate the CPU has finished processing its physical buffer. This bit is automatically cleared by hardware, reads always return 0.  0x0: No effect. 0x1: The CPU has completely processed the CPUW physical buffer.	W	0x0

Bits	Field Name	Description	Type	Reset
1	RWMODE	Selects read or write mode  0x0: Write mode. HW writes and CPU reads the physical space. CPU accesses are out of CBUFF module's scope, therefore only writes are permitted between CBUFF0_START and CBUFF0_END.  0x1: Read mode. HW reads and CPU writes the physical space. CPU accesses are out of CBUFF module's scope; therefore only reads are permitted between CBUFF0_START and CBUFF0_END.	RW	0x0
0	ENABLE	Enable/disable  0x0: Disables the circular buffer 0; this resets the internal state of circular buffer 0. All accesses received on OCPI are transmitted to OCPO without modification. Disabling the module takes effect immediately. It is SW responsibility to ensure that no more accesses to CBUFF0 are outstanding before disabling the module. Otherwise memory corruption may occur.  0x1: Enable the circular buffer 0. All accesses between CBUFF0_START and CBUFF0_END are processed by the module.	RW	0x0

#### 12.6.4.2 Camera ISP\_CSIB1 Register Description

**Table 12-130. CSI1B\_REVISION**

<b>Address Offset</b>	0x0000 0000	<b>Instance</b>	ISP ISP_CSI1B
<b>Physical Address</b>	0x480B C400 0x480B C400		
<b>Description</b>	MODULE REVISION This register contains the IP revision code in binary coded digital. For example, we have: 0x01 = revision 0.1 and 0x21 = revision 2.1		
<b>Type</b>	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																REV															

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Write 0s for future compatibility. Reads returns 0.	R	0x000000
7:0	REV	IP revision [7:4] Major revision [3:0] Minor revision	R	TI internal data

**Table 12-131. Register Call Summary for Register CSI1B\_REVISION**

Camera ISP Register Manual

- [Camera ISP\\_CSI1B Register Summary: \[0\]](#)

**Table 12-132. CSI1B\_SYSCONFIG**

<b>Address Offset</b>	0x0000 0004	<b>Instance</b>	ISP
<b>Physical Address</b>	0x480B C404 0x480B C404		ISP_CSI1B
<b>Description</b>	SYSTEM CONFIGURATION REGISTER This register is the CSI1 system configuration register.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																MSTANDBY_MODE		RESERVED										SOFT_RESET	AUTO_IDLE		

Bits	Field Name	Description	Type	Reset
31:14	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0000
13:12	MSTANDBY_MODE	Sets the behavior of the master port power management signals.  0x0: Force-standby. Hardware signal is only asserted when the module is disabled.  0x1: No-standby. Hardware signal is never asserted.  0x2: Smart-standby: Hardware signal is asserted based on the activity of the module. The module tries to go to standby during the vertical blanking period.	RW	0x0
11:2	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x000
1	SOFT_RESET	Software reset. Set the bit to 1 to trigger a module reset. The bit is automatically reset by the HW. During reads return 0.  0x0: Normal mode.  0x1: The module is reset	RW	0x0
0	AUTO_IDLE	Internal interface clock gating strategy.  0x0: Interface clock is free-running.  0x1: Automatic Interface clock gating strategy is applied based on the Interconnect interface activity.	RW	0x1

**Table 12-144. CSI1B\_CTRL**

<b>Address Offset</b>	0x0000 0040		
<b>Physical Address</b>	0x480B C440 0x480B C440	<b>Instance</b>	ISP ISP_CSI1B
<b>Description</b>	GLOBAL CONTROL REGISTER This register controls the CSI1 RECEIVER module. This register must not be modified dynamically (except IF_EN bit field).		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																VP_CLK_POL	VP_ONLY_EN	INV	VP_OUT_CTRL	DBG_EN	BURST	RESERVED	FRAME	IO_OUT_SEL	PHY_SEL	IF_EN					

Bits	Field Name	Description	Type	Reset
31:13	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x00000
12	VP_CLK_POL	VP clock polarity  0x0: The RECEIVER module writes the data on the VP on the pixel clock falling edge. The module connected to the VP must sample the data on the pixel clock rising edge.  0x1: The RECEIVER module writes the data on the VP on the pixel clock raising edge. The module connected to the VP must sample the data on the pixel clock falling edge.	RW	0x0
11	VP_ONLY_EN	VP only enable.  0x0: The VP is enabled and the Interconnect master port are enabled.  0x1: The VP is enabled and the Interconnect master port is disabled. The embedded data and pixel data are output on the VP.	RW	0x0
10	INV	Strobe/clock inversion control signal  0x0: Not inverted. 0x1: Inverted.	RW	0x0
9:8	VP_OUT_CTRL	Video port output clock control. Sets the video port output clock as a function of the interface clock (OCPCLK).  0x0: No division: video port clock = OCPCLK. 0x1: Division by 2: video port clock = OCPCLK/2. 0x2: Division by 3: video port clock = OCPCLK/3. 0x3: Division by 4: video port clock = OCPCLK/4.	RW	0x1
7	DBG_EN	Enables the debug mode.  0x0: Disable 0x1: Enable	RW	0x0
6:5	BURST	Forces the write burst size used by the module. The write burst size must never exceed the output FIFO size. The output FIFO size can be read with the CSI1_GNQ.FIFODEPTH bit field.  0x0: 1x 64-bit burst = single request. 0x1: 2x 64-bit bursts. 0x2: 4x 64-bit bursts. 0x3: 8x 64-bit bursts.	RW	0x0
4	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
3	FRAME	Set the modality in which IF_EN works.  0x0: When SW writes IF_EN = 0 the interface is disabled immediately.  0x1: When SW writes IF_EN = 1 the interface is disabled after the next FEC sync code.	RW	0x0
2	IO_OUT_SEL	I/O cell output mode selection.  0x0: I/O output is serial: DATA, STROBE  0x1: I/O output is parallel: DATA32, DATATOG, SYNTOG. Note that the SSC_IRQ error cannot be triggered in this configuration.	RW	0x0
1	PHY_SEL	Physical layer protocol selection.  0x0: Data/Clock physical layer 0x1: Data/Strobe physical layer	RW	0x0

Bits	Field Name	Description	Type	Reset
0	IF_EN	Enables the physical interface to the module.  0x0: The interface is disabled. If FRAME = 0, it is disabled immediately. If FRAME = 1, it is disabled on the next FEC sync code.  0x1: The interface is enabled immediately, the data acquisition starts on the next FSC sync code. Writing 1 to this register when the current value is 0 has the effect to clear the output FIFO. The pixel data of the following frame is written in the PING buffer, that is, the CSI1_CTRL.PING_PONG bits are reset to 1 as well.	RW	0x0

<b>Address Offset</b>	0x0000 0078	
<b>Physical Address</b>	0x480B C478 0x480B C478	<b>Instance</b> ISP ISP_CSI1B
<b>Description</b>	DATA MEM ADDRESS OFFSET REGISTER This register sets the offset, which is applied on the destination address after each line is written to memory. This register applies for both CSI1_DAT_PING_ADDR and CSI1_DAT_PONG_ADDR. For example, it enables to perform 2D data transfers of the pixel data into a frame buffer. In such case, the pixel data and frame buffer data must have the same data format. Note that the 5 LSBs are ignored: the offset must be a multiple of 32 bytes. The usage of this register is limited to the following data formats: YUV422 LITTLE ENDIAN, YUV422 BIG ENDIAN, RGB565, RGB444 + EXP16, RGB888 + EXP32. This register is shadowed: modifications are taken into account after the next FSC sync code.	
<b>Type</b>	RW

**Table 12-176. CSI1B\_LCM\_HSIZE**

<b>Address Offset</b>	0x0000 01D8		
<b>Physical Address</b>	0x480B C5D8 0x480B C5D8	<b>Instance</b>	ISP ISP_CSI1B
<b>Description</b>	Memory read channel horizontal framing register.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								COUNT								RESERVED				SKIP											

Bits	Field Name	Description	Type	Reset
31:28	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
27:16	COUNT	Horizontal count of pixels to output after the skipped pixels. Valid values: 1-4095.	RW	0x000
15:12	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
11:0	SKIP	Horizontal count of pixels to skip after the start of the line. Valid values: 0-4095. 0 disables pixel skipping	RW	0x000

<b>Address Offset</b>	0x0000 01E4	
<b>Physical Address</b>	0x480B C5E4 0x480B C5E4	<b>Instance</b> ISP ISP_CSI1B
<b>Description</b>	Memory channel source offset register. This register sets the offset, which is applied on the source address after each line is read from memory. For example, it enables to perform 2D data transfers of the pixel data from a frame buffer. In such case, the pixel data and frame buffer data must have the same data format. Note that the 5 LSBs are ignored: the offset must be a multiple of 32 bytes.	
<b>Type</b>	RW	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OFST																RESERVED															

Bits	Field Name	Description	Type	Reset
31:5	OFST	Line offset programmed in bytes. If OFST = 0, the data is read contiguously from memory. Otherwise, OFST sets the source offset between the first pixel of the previous line and the first pixel of the current line.	RW	0x0000000
4:0	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x00

**Table 12-193. CCDC\_SYN\_MODE**

<b>Address Offset</b>	0x0000 0008	<b>Instance</b>	ISP ISP_CCDC
<b>Physical Address</b>	<a href="#">0x480B C608</a> <a href="#">0x480B C608</a>		
<b>Description</b>	SYNC and mode set register		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								SDR2RSZ	VP2SDR	WEN	VDHLEN	FLDSTAT	LPF	INPMOD	PACK8	DATSIZ				FLDMODE	DATAPOL	EXWEN	FLDPOL	HPOL	VPOL	FLDOUT	VDHOUT				

Bits	Field Name	Description	Type	Reset
31:20	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x000
19	SDR2RSZ	Memory port output into the RESIZER input. Controls whether or not the memory port output data are forwarded to the RESIZER module input port. This does not depend on the state of the <a href="#">CCDC_SYN_MODE.WEN</a> bit. This bit must only be set if the CCDC module receives directly YUV422 data. The input frame size to the RESIZER module is the same as the output frame size to the memory port. The data are simultaneously written to memory if the WEN bit is set while sending the same data to the RESIZER module. The PREVIEW module can also write to the RESIZER module: this bit takes precedence over the PREVIEW module settings. This bit is latched by the VS sync pulse.  0x0: Disable 0x1: Enable	RW	0x0
18	VP2SDR	Video port output enable to the output formatter.. Controls whether the video port data is forwarded to the output formatter or not. If <a href="#">CCDC_SYN_MODE.WEN</a> = 1, the video port data is written to memory. Note that if field is set, then SDRAM line (VERT_START.SLVx) and pixel start (HORZ_INFO.SPH) are with respect to the video port output (and not the original input) This bit field is latched by the VS sync pulse.  0x0: Disable 0x1: Enable	RW	0x0

Bits	Field Name	Description	Type	Reset
17	WEN	Data write enable. Controls whether the CCDC module output data are written to memory or not. This bit field is latched by the VS sync pulse. 0x0: Disable 0x1: Enable	RW	0x0
16	VDHDEN	Timing generator enable. If HS/VS sync pulses are defined as output signals, activates the internal timing generator. If HS/VS sync pulses are defined as input signals, activates internal timing generator to synchronize with HS/VS. This bit must be set to 1 when HS and VS signals are used. 0x0: Disable 0x1: Enable	RW	0x0
15	FLDSTAT	cam_fld signal status. This bit field applies only if the CCDC module is configured to work in interlaced mode: <a href="#">CCDC_SYN_MODE.FLDMODE</a> = "interlaced". It indicates the status of the current field. 0x0: Odd field 0x1: Even field	R	0x0
14	LPF	Three-tap low pass (antialiasing) filter enable. This bit field is latched by the VS sync pulse. 0x0: Filter is disabled. 0x1: Filter is enabled.	RW	0x0
13:12	INPMOD	cam_d format in SYNC mode. Sets the data input format. 0x0: Raw data 0x1: YCbCr data on 16 bits. It is required to enable the 8 to 16-bit bridge in the <a href="#">ISP_CTRL</a> register. 0x2: YCbCr data on 8 bits.	RW	0x0
11	PACK8	Data packing. Sets the data packing configuration when the data is written to memory. 0x0: Normal mode: 16 bits/pixel. 0x1: Pack mode: 8 bits/pixel.	RW	0x0
10:8	DATSIZ	cam_d signal width in SYNC mode. Valid only when <a href="#">CCDC_SYN_MODE.INPMOD</a> = "raw data". 0x0: cam_d is 8 bits but the 8 to 16-bit bridge is enabled in the <a href="#">ISP_CTRL</a> register. 0x4: cam_d is 12 bits 0x5: cam_d is 11 bits 0x6: cam_d is 10 bits 0x7: cam_d is 8 bits	RW	0x0
7	FLDMODE	cam_fld signal mode. 0x0: Progressive mode. cam_fld not used. 0x1: Interlaced mode. cam_fld used.	RW	0x0
6	DATAPOL	cam_d signal polarity. 0x0: Normal 0x1: One's complement	RW	0x0

Bits	Field Name	Description	Type	Reset
5	EXWEN	External write enable selection. The cam_wen signal can be used as an external memory write-enable signal. The data is stored to memory only if cam_hs, cam_vs and cam_wen signals are asserted. 0x0: cam_wen is not used. 0x1: cam_wen is used	RW	0x0
4	FLDPOL	cam_fld signal polarity. 0x0: Positive 0x1: Negative	RW	0x0
3	HDPOL	Sets the cam_hs signal polarity. 0x0: Positive 0x1: Negative	RW	0x0
2	VDPOL	cam_vs signal polarity 0x0: Positive 0x1: Negative	RW	0x0
1	FLDOUT	cam_fld signal direction. 0x0: Input 0x1: Output	RW	0x0
0	VDHDOUT	cam_hs and cam_vs signal directions. 0x0: Input 0x1: Output	RW	0x0

<b>Address Offset</b>	0x0000 0010	<b>Instance</b>	ISP
<b>Physical Address</b>	0x480B C610 0x480B C610		ISP_CCDC
<b>Description</b>	SIZE CONTROL REGISTER		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PPLN																HLPRF															

Bits	Field Name	Description	Type	Reset
31:16	PPLN	Pixels per line Sets the number of pixel clock periods in one line. HD period = (PPLN + 1) pixel clocks. Not used when HS/VS sync pulses are input signals (CCDC_SYN_MODE.VDHDOUT = 0). This bit field is latched by the VS sync pulse	RW	0x0000

Bits	Field Name	Description	Type	Reset
15:0	HLPFR	Half line per field or frame Sets the number of half lines per frame or field. VD period = (HLPFR + 1)/2 lines. Not used when HS/VS sync pulses are input signals (CCDC_SYN_MODE.VDHDOUT = 0). Sets the internal timing generator to generate the correct number of HS pulses in between two VS pulses. If the sensor is interlaced, with a total of N lines, then this field must be set to N. This means that N half lines are written for each field. If the sensor is progressive, then this register must be set to be twice the number of lines to be written. For example, if sensor outputs N lines, this field must be set to 2N. This bit field is latched by the VS sync pulse.	RW	0x0000

<b>Address Offset</b>	0x0000 0040	<b>Instance</b>	ISP ISP_CCDC
<b>Physical Address</b>	0x480B C640 0x480B C640		
<b>Description</b>	FAULT PIXEL CORRECTION REGISTER		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																FPER	FPCEN	FPNUM													

Bits	Field Name	Description	Type	Reset
31:17	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0000
16	FPERR	<p>Fault pixel correction error</p> <p>This bit is set when the CCDc module is unable to fetch the required fault pixel table entry in time. Write 1 to clear the error or end_of_frame clears it automatically for the next frame.</p> <p>For example, the current pixel being processed has coordinates of 256/512 (256th line and 512th pixel in that line) and it must be corrected. If the entry in the fault pixel table that must be used has coordinates 256/256, then the current pixel cannot be corrected since the correct entry is not loaded in time.</p> <p>Note that there is no error recovery mechanism in the CCDc; if this bit is set at anytime in a frame, there are no more fault pixels corrected in that frame. Firmware is responsible for making sure that there is enough bandwidth in the system to allow for loading of the fault pixel table. Alternately, decreasing the frequency of the fault pixels to be corrected enhances the chances of this bit not being set.</p> <p>0x0: No error 0x1: Error</p>	RW	0x0
15	FPCEN	<p>Fault pixel correction enable.</p> <p>Upon setting this bit, and as long as it remains enabled, the fault pixel logic continues to request data and just start over for next frame once the last data of current frame has been received. As soon as the register is set the data are fetched. To disable fault pixel correction, users can write a 0 at any time. However, the disabling only applies after the current frame is processed (busy bit for current frame is 0)</p> <p>This bit should only be written after the FPC_ADDR register below has been set. Also, the other fields in this register have to be set prior to enabling this bit. The required process is: Write(FPC_ADDR) Write(FPC) with this bit (FPC.FPCEN) turned off Write(FPC) with this bit (FPC.FPCEN) turned on while other fields are same as previous write</p> <p>0x0: Disable 0x1: Enable</p>	RW	0x0
14:0	FPNUM	<p>Number of fault pixels to be corrected in the frame</p> <p>This field should not be changed when the FPCEN is enabled at any time</p>	RW	0x0000

RESERVED												VPIF_FRQ	VPEN	VPIN	PLEN_EVEN	PLEN_ODD	LNUM	LNALT	FMTEN												

Bits	Field Name	Description	Type	Reset
31:19	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0000
18:16	VPIF_FRQ	Video port data ready frequency.  This field allows the firmware to control the rate at which the video port delivers new data to the other modules (PREVIEW, H3A, and HIST modules).  In effect, this register controls the raw output bandwidth of the PREVIEW, H3A, and HIST. Depending on the input sensor clock, users can set this field appropriately and balance the bandwidth requirements to memory.  Given a pixel clock, one must set this bit field with the higher divisor value to lower the memory bandwidth requirement.  The video port clock is $\text{interconnect}/(\text{VPIF\_FRQ}+2)$ . The valid range for VPIF FRQ is 0..6	RW	0x0
15	VPEN	Video port enable. This bit must be enabled to send data to the PREVIEW, H3A and HIST modules.  0x0: Disable 0x1: Enable	RW	0
14:12	VPIN	10-bit input select for video port.  0x3: bits 12-3 0x4: bits 11-2 0x5: bits 10-1 0x6: bits 9-0	RW	0x4
11:8	PLEN_EVEN	Number of program entries in even line minus 1. If the desired number of program entries is 8, then the value must be set to 7.	RW	0x0
7:4	PLEN_ODD	Number of program entries in odd line minus 1. If the desired number of program entries is 8, then the value must be set to 7.	RW	0x0

Bits	Field Name	Description	Type	Reset
3:2	LNUM	Number of output lines from 1 input line 0x0: 1 line 0x1: 2 lines 0x2: 3 lines 0x3: 4 lines	RW	0x0
1	LNALT	Line alternating mode enable. In Line Alternating Mode, even and odd lines are swapped. 0th line output as 1st line and 1st line output as 0th line, and so on. If this bit field is set, the start and number of lines for the formatter (FMTVERT below) must be even. The FMTEN field below must be set in addition for this field to function 0x0: Enable. Normal mode 0x1: Disable. Line alternating mode	RW	0x0
0	FMTEN	Formatter enable. This bit is latched by the VS sync pulse. 0x0: Disable 0x1: Enable	RW	0x0

<b>Address Offset</b>	0x0000 0094		
<b>Physical Address</b>	0x480B C694 0x480B C694	<b>Instance</b>	ISP ISP_CCDC
<b>Description</b>	VIDEO PORT OUTPUT REGISTER		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED	VERT_NUM											HORZ_NUM											HORZ_ST								

Bits	Field Name	Description	Type	Reset
31	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
30:17	VERT_NUM	Number of vertical lines to clock out the video. If the data reformatter is turned off, then the number of lines that can be clocked out of the video port must be at least 1 line less than the number of lines input from the sensor. If the data reformatter is turned on, then the number of lines that can be clocked out of the video port must be less than (CCDC_FMT_VERT.FMTLNV - 1) * (CCDC_FMTCFG.LNUM + 1) The video port output VS pulse is generated right from the first video port input VS itself.	RW	0x0000
16:4	HORZ_NUM	Number of horizontal pixel to clock out the video port. The minimum value allowed is 2 pixels. The maximum offset allowed is 1376 if original input is broken down to 4 lines. The maximum offset allowed is 1376 if original input is broken down to 3 lines. The maximum offset allowed is 2*1376 if original input is broken down to 2 lines. The maximum offset allowed is 4*1376 if original input is broken down to 1 line.	RW	0x0000
3:0	HORZ_ST	Horizontal start pixel in each output line. The maximum value allowed is 15. The video port output HSYNC pulse is generated from this position on for each line. To be able to select an offset higher than 15, the input settings to the data reformatter must be configured appropriately. The purpose of this parameter is to allow for sensors that can read out a parallelogram image rather than a rectangular image.	RW	0x0

RESERVED																GAIN_MODE_M		RESERVED	GAIN_MODE_N		BUSY	AFTER_REFORMATTER	RESERVED	GAIN_FORMAT		ENABLE					

Bits	Field Name	Description	Type	Reset
31:15	RESERVED	Write 0s for future compatibility. Read returns zero.	RW	0x00000
14:12	GAIN_MODE_M	Define the horizontal dimension of a paxel. Possible values are listed below 0x2: Paxel is 4 pixels tall (M=4) 0x3: Paxel is 8 pixels tall (M=8) 0x4: Paxel is 16 pixels tall (M=16) 0x5: Paxel is 32 pixels tall (M=32) 0x6: Paxel is 64 pixels tall (M=64)	RW	0x6
11	RESERVED	Write 0s for future compatibility. Read returns zero.	R	0x0
10:8	GAIN_MODE_N	Define the vertical dimension of a paxel. Possible values are listed below 0x2: Paxel is 4 pixels tall (N=4) 0x3: Paxel is 8 pixels tall (N=8) 0x4: Paxel is 16 pixels tall (N=16) 0x5: Paxel is 32 pixels tall (N=32) 0x6: Paxel is 64 pixels tall (N=64)	RW	0x6
7	BUSY	Module busy or idle 0x0: The module is idle 0x1: The module is busy	R	0x0
6	AFTER_REFORMATTER	Chooses if lens-shading compensation is done before or after data reformatting 0x0: Lens-shading is done before data reformatting. H3A, HIST and PREVIEW receives shading compensated data 0x1: Data received by H3A isn't compensated. Data received by PREVIEW and HIST is compensated.	RW	0x0
5:4	RESERVED	Write 0s for future compatibility. Reads return zero.	RW	0x0
3:1	GAIN_FORMAT	Sets gain table format 0x0: Coded as 8-bit fraction Range from 0 to 255/256 0x1: Coded as 8-bit fraction + 1.0 of base. Range from 1 to 1+255/256 0x2: Coded as 1-bit integer, 7-bit fraction. Range from 0 to 1+127/128 0x3: Coded as 1-bit integer, 7-bit fraction + 1.0 Range from 1 to 2+127/128 0x4: Coded as 2-bit integer, 6-bit fraction Range from 0 to 3+63/64 0x5: Coded as 2-bit integer, 6-bit fraction + 1.0 Range from 1 to 4+63/64 0x6: Coded as 3-bit integer, 5-bit fraction Range from 0 to 7+31/32 0x7: Coded as 3-bit integer, 5-bit fraction + 1.0 Range from 1 to 8+31/32	RW	0x0
0	ENABLE	Enables/disables LSC 0x0: Disables the module at the end of the current frame. Video data is transmitted without modification when LSC is disabled. The BUSY bit can be used to poll when access to SBL buffer can be used by the preview module. 0x1: Enables the module. Module starts fetching the gain table as soon it is started. Firmware has to make sure it has been correctly initialized before starting the module. Data processing is only effective at the start of the next frame. Note that preview module dark frame subtract must be disabled because there is only one shared read port.	RW	0x0

**Table 12-334. PRV\_PCR**

<b>Address Offset</b>	0x0000 0004		
<b>Physical Address</b>	0x480B CE04 0x480B CE04	<b>Instance</b>	ISP ISP_PREVIEW
<b>Description</b>	PERIPHERAL CONTROL REGISTER All the fields in this register can be altered even when the PREVIEW module is busy. Changes take place only for the next frame.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DRK_FAIL	RESERVED	DCOR_METHOD	DCOREN	GAMMA_BYPASS	RESERVED	SCOMP_SFT	SCOMP_EN	SDRPORT	RSZPORT	YCPOS	SUPEN	YNENHEN	CFAFMT				CFAEN	NFEN	HMEDEN	DRKFCAP	DRKFEN	INVALAW	WIDTH	ONESHOT	SOURCE	BUSY	ENABLE				

Bits	Field Name	Description	Type	Reset
31	DRK_FAIL	Dark frame subtract fail status. Write 1 to clear this bit. Reset to zero for the next frame. When the error is triggered, dark frame subtract is abandoned for the current frame, dark frame subtract resumes for next frame (but bit is not cleared unless explicitly done by firmware). 0x0: No error 0x1: Error	RW	0x0
30:29	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
28	DCOR_METHOD	Defect correction method. 0x0: MinMax 0x1: MinMax2 (Couplet defect correction)	RW	0x0

Bits	Field Name	Description	Type	Reset
27	DCOREN	Defect correction enable This bit enables or disables the defect correction. The <a href="#">PRV_PCR.DCOR_METHOD</a> and <a href="#">PRV_CDC_THRx</a> registers must be configured for correct operation. 0x0: Disable defect correction 0x1: Enable defect correction	RW	0x0
26	GAMMA_BYPASS	Bypass, the output is set to the 8 MSB of the 10-bit input. 0x0: No bypass. 0x1: Bypass, the output is set to the 8 MSB of the 10-bit input.	RW	0x0
25	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
24:22	SCOMP_SFT	Shading compensation shift value after multiplication. The right-shift range is 0 to 7.	RW	0x0
21	SCOMP_EN	Shading compensation enable instead of dark frame The 8-bit value loaded from memory is multiplied by the current pixel instead of subtracting it. Note that the dark frame subtract (DRKFEN) must be enabled in addition to this bit being active to perform shading compensation. 0x0: Disable. Dark frame subtract can be used. 0x1: Enable. Dark frame subtract cannot be used.	RW	0x0
20	SDRPORT	PREVIEW module memory output port enable. This bit enables or disables the data transfer from the PREVIEW module to the memory. 0x0: Disable 0x1: Enable	RW	0x1
19	RSZPORT	RESIZER module output port enable. This bit enables or disables the data transfer between the PREVIEW and RESIZER modules. Controls whether or not SDRAM output data is forwarded to the resizer input port. This control bit does not depend on the state of the former SDRPORT bit. Data is simultaneously written to SDRAM (if SDRPORT bit is set) while sending the same data to the resizer as input. Note that the CCDC is also capable of directly writing to the resizer input port. The CCDC setting takes precedence over the preview engine setting. 0x0: Disable 0x1: Enable	RW	0x0
18:17	YCPOS	(CRYCBy) Cr0(31:24) Y1(23:16) Cb0(15:8) Y0(7:0) 0x0: (YCRYCb) Y1(31:24) Cr0(23:16) Y0(15:8) Cb0(7:0) 0x1: (YCbYCR) Y1(31:24) Cb0(23:16) Y0(15:8) Cr0(7:0) 0x2: (CbYCRY) Cb0(31:24) Y1(23:16) Cr(15:8) Y0(7:0) 0x3: (CRYCBy) Cr0(31:24) Y1(23:16) Cb0(15:8) Y0(7:0)	RW	0x0
16	SUPEN	Color suppression. 0x0: Disable 0x1: Enable	RW	0x0
15	YNENHEN	Non-linear enhancer 0x0: Disable 0x1: Enable	RW	0x0

Bits	Field Name	Description	Type	Reset
14:11	CFAFMT	CFA format 0x0: Mode 0: conventional Bayer. 0x1: Mode 1: horizontal 2x downsample. 0x2: Mode 2: bypass CFA stage 0x3: Mode 3: horizontal and vertical 2x downsample. 0x4: Mode 4: Super CCD Honeycom movie mode sensor. 0x5: Mode5: bypass CFA stage .	RW	0x0
10	CFAEN	CFA enable 0x0: Disable 0x1: Enable	RW	0x0
9	NFEN	Noise filter enable 0x0: Disable 0x1: Enable	RW	0x0
8	HMEDEN	Horizontal median filter enable. 0x0: Disable 0x1: Enable	RW	0x0
7	DRKFCAP	Dark frame capture enable. 0x0: Normal processing. 0x1: Capture dark frame.	RW	0x0
6	DRKFEN	Subtract dark frame enable. 0x0: Disable 0x1: Enable	RW	0x0
5	INVALAW	Inverse A-Law enable. 0x0: Disable 0x1: Enable	RW	0x0
4	WIDTH	Input data width selection. 0x0: 10-bit mode 0x1: 8-bit mode	RW	0x0
3	ONESHOT	One-shot mode selection. If this bit is set to 1, it is reset to 0 after the ENABLE bit is asserted. 0x0: Continuous mode (through the video port). 0x1: One shot mode.	RW	0x0
2	SOURCE	Input source selection. If this bit is set to 1, it is reset to 0 after the ENABLE bit is asserted. 0x0: Video port (through the CCDC) 0x1: Memory.	RW	0x0
1	BUSY	Busy bit. 0x0: PREVIEW module not busy. 0x1: PREVIEW module busy.	R	0x0
0	ENABLE	Enable bit. If the ONESHOT or SOURCE bit is 1, this bit is reset to 0 after it is asserted 0x0: PREVIEW module disabled. 0x1: PREVIEW module enabled.	RW	0x0

<b>Description</b>	PERIPHERAL CONTROL REGISTER		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																ONESHOT	BUSY	ENABLE													

Bits	Field Name	Description	Type	Reset
31:3	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x00000000
2	ONESHOT	One-shot or continuous mode selection. This bit only applies when the image source is CCDC or PREVIEW ( <i>RSZ_CNT</i> INPSRC =0)  0x0: Continuous mode. The module must be disabled by software. The disable module is latched at the end of the frame it was written in.  0x1: One shot mode. Enable bit is reset to 0 once the busy bit turns to 1.	RW	0x1
1	BUSY	RESIZER module busy.  0x0: RESIZER module not busy.  0x1: RESIZER module busy.	R	0x0

Bits	Field Name	Description	Type	Reset
0	ENABLE	RESIZER module enable. Memory to memory operation: Resizer always operates in one-shot mode in memory to memory operation. Enable bit is reset to 0 once the busy bit turns to 1. CCDC/PREVIEW to memory operation: The resizer operates either in one-shot or continuous mode. The behavior is defined by the <a href="#">RSZ_PCR</a> [2] ONESHOT bit. The enable bit MUST be the last field written to resize a frame. The enable bit can be written when the resizer is busy. 0x0: Disable RESIZER module. 0x1: Enable RESIZER module.	RW	0x0

<b>Physical Address</b>	<a href="#">0x480B D008</a> <a href="#">0x480B D008</a>		
<b>Description</b>	RESIZER CONTROL REGISTER		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
RESERVED	CBILIN	INPSRC	INPTYP	YCPOS	VSTPH	HSTPH										VRSZ																HRSZ

Bits	Field Name	Description	Type	Reset
31:30	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
29	CBILIN	Chrominance horizontal algorithm select. Filtering that is same as luminance processing is intended only for downsampling, and bilinear interpolation is intended only for upsampling. 0x0: The chrominance uses the same processing as the luminance. 0x1: The chrominance uses bilinear interpolation processing.	RW	0x0

Bits	Field Name	Description	Type	Reset
28	INPSRC	Input source select. NOTE: If this field is set to zero, the resizer input is fed from either the preview engine or the CCDC, but not both. The CCDC and preview engine modules have individual control to feed their output to the resizer input. If both the CCDC and preview engine modules are set to drive the resizer input, the CCDC output takes precedence. 0x0: PREVIEW or CCDC module. 0x1: Memory.	RW	0x0
27	INPTYP	Input type select. 0x0: YUV422 color is interleaved 0x1: Color separate data on 8 bits.	RW	0x0
26	YCPOS	Luminance and chrominance position in 16-bit word 0x0: YC 0x1: CY	RW	0x0
25:23	VSTPH	Vertical starting phase. The phase range is 0 to 7.	RW	0x0
22:20	HSTPH	Horizontal starting phase. The phase range is 0 to 7.	RW	0x0
19:10	VRSZ	Vertical resizing value. (range from 64 - 1024) plus 1 Vertical resizing ratio is $256/(VRSZ+1)$ For have the correct functionality, must enter the desired value minus 1. For example for a ratio of 1, must enter 255	RW	0x0FF
9:0	HRSZ	Horizontal resizing value. (range from 64 - 1024) plus 1 Horizontal resizing ratio is $256/(HRSZ+1)$ For have the correct functionality, must enter the desired value minus 1. For example for a ratio of 1, must enter 255	RW	0x0FF

<b>Address Offset</b>	0x0000 0010	<b>Instance</b>	ISP
<b>Physical Address</b>	0x480B D010 0x480B D010		ISP_RESIZER
<b>Description</b>	INPUT CONFIGURATION REGISTER This register must be used when the input pixel data comes from the PREVIEW module. must be set to 0 is the input pixel data comes from memory.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								VERT_ST								RESERVED				HORZ_ST											

Bits	Field Name	Description	Type	Reset
31:29	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
28:16	VERT_ST	Vertical start line. This field makes sense when the resizer obtains its input from the preview engine/CCDC When the resizer gets its input from SDRAM, this field must be set to 0	RW	0x0000
15:13	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
12:0	HORZ_ST	Horizontal start pixel. Pixels are coded on 16 bits for YUV and 8 bits for color separate data. When the resizer gets its input from SDRAM, this field must be set to = 15 for YUV 16-bit data and = 31 for 8-bit color separate data Horizontal starting pixel value is in number of pixels if input is from SDRAM. If the input to the resizer is from CCDC/preview engine, this field must be programmed as follows: (1) Program this field using number of bytes (twice number of pixels). (2) Change the lowest bit to reflect start position in pixels (effectively change from a value 0 to a value 1 if required)	RW	0x0000

<b>Description</b>	INPUT ADDRESS REGISTER This register must be set only if the input pixel data comes from memory.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADDR																															

Bits	Field Name	Description	Type	Reset
31:0	ADDR	32-bit input memory address. The 5 LSBs are forced to be zeros by the hardware to align on a 32-byte boundary; the 5 LSBs are read-only. This field must be programmed to be 0x0 if the resizer input is from preview engine/CCDC. * This field can be altered even when the resizer is busy. The change takes place only for the next frame. However, note that reading this register always gives the latest value.	RW	0x00000000

<b>Physical Address</b>	<a href="#">0x480B D204</a> <a href="#">0x480B D204</a>		
<b>Description</b>	PERIPHERAL CONTROL REGISTER Note on the overflow bits: the overflow does not prevent the modules to make further requests. The only way to clear the overflow is to reset the bit. After an overflow, the data are corrupted and the application layer should disregard the data. No software reset is required after an overflow. If the overflow condition is cleared, the data continue to be acquired normally.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bits	Field Name	Description	Type	Reset
31:27	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x00
26	CSIB_WBL_OVF	CSIB Write buffer memory overflow All DUs have been filled up: overflow. Software has to write 1 to clear the bit.  0x0: No overflow 0x1: Overflow	RW	0x0
25	CSIA_WBL_OVF	CSIA Write buffer memory overflow All DUs have been filled up: overflow. Software has to write 1 to clear the bit.  0x0: No overflow 0x1: Overflow	RW	0x0

Bits	Field Name	Description	Type	Reset
24	CCDCPRV_2_RSZ_OVF	<p>CCDC/PRV to RESIZER input overflow</p> <p>This bit is set if the RESIZER input source is set to CCDC/PREVIEW engine when the active data (to be resized) has already showed up at the resizer interface. In such a case, resizing for this frame cannot take place and the bit is set. This scenario can happen when a resize of 4x is required per frame. Therefore, the RESIZER needs to operate in two passes. In the first pass the input data from CCDC/PREVIEW is directly resized and written to memory. In the second pass, the resized data from the first pass is resized again. The next frame from the CCDC/PREVIEW engine should only start after the second pass on the previous frame is complete. This bit indicated the failure status.</p> <p>Software has to write 1 to clear the bit.</p> <p><b>Note:</b> Ignore the behavior of this field when <code>RSZ_CNT[28] INPSRC = 0x1</code> (when data comes from memory).</p> <p>0x0: No overflow 0x1: Overflow</p>	RW	0x0

**Table 12-619. CSI2\_SYSCONFIG**

<b>Address Offset</b>	0x0000 0010		
<b>Physical Address</b>	0x480B D810 0x480B D810	<b>Instance</b>	ISP ISP_CSI2A
<b>Description</b>	SYSTEM CONFIGURATION REGISTER This register is the OCP-socket system configuration register.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																MSTANDBY_MODE		RESERVED										SOFT_RESET	AUTO_IDLE		

Bits	Field Name	Description	Type	Reset
31:14	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x00000
13:12	MSTANDBY_MODE	Sets the behavior of the master port power management signals.  0x0: Force-standby. Hardware signal is only asserted when the module is disabled.  0x1: No-standby. Hardware signal is never asserted.  0x2: Smart-standby: Hardware signal is asserted based on the activity of the module. The module tries to go to standby during the vertical blanking period.	RW	0x0
11:2	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x000
1	SOFT_RESET	Software reset. Set the bit to 1 to trigger a module reset. The bit is automatically reset by the HW. During reads return 0.  0x0: Normal mode. 0x1: The module is reset. <sup>(1)</sup>	RW	0x0
0	AUTO_IDLE	Internal OCP gating strategy  0x0: OCP clock is free-running.  0x1: Automatic OCP clock gating strategy is applied based on the OCP interface activity.	RW	0x1

<sup>(1)</sup> Before setting the software reset bit to 1 in the CSI2\_SYSCONFIG register, the user must have access to a CSI2 receiver register.

<b>Description</b>	INTERRUPT ENABLE REGISTER - All contexts This register associates one bit for each context to enable/disable each context individually.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0																
RESERVED																																															

Bits	Field Name	Description	Type	Reset
31:15	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x00000
14	OCP_ERR_IRQ	OCP Error Interrupt 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
13	SHORT_PACKET_IRQ	Short packet reception (other than sync events: Line Start, Line End, Frame Start, and Frame End: data type between 0x8 and x0F only must be considered). 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
12	ECC_CORRECTION_IRQ	ECC has been used to correct the only 1-bit error (short packet only). 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
11	ECC_NO_CORRECTION_IRQ	ECC error (short and long packets). No correction of the header because of more than 1-bit error. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
10	RESERVED	Reserved	RW	0x0
9	COMPLEXIO1_ERR_IRQ	Error signaling from Complex I/O #1: the interrupt is triggered when any error is received from the complex I/O #1 (events are defined in <a href="#">CSI2_COMPLEXIO1_IRQSTATUS</a> for the 1st complex I/O). 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
8	FIFO_OVF_IRQ	FIFO overflow enable 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
7	CONTEXT7	Context 7 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
6	CONTEXT6	Context 6 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
5	CONTEXT5	Context 5 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
4	CONTEXT4	Context 4 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
3	CONTEXT3	Context 3 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
2	CONTEXT2	Context 2 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
1	CONTEXT1	Context 1 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0

Bits	Field Name	Description	Type	Reset
0	CONTEXT0	Context 0 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0

<b>Address Offset</b>	0x0000 0040	<b>Instance</b>	ISP ISP_CSI2A
<b>Physical Address</b>	<a href="#">0x480B D840</a> <a href="#">0x480B D840</a>		
<b>Description</b>	GLOBAL CONTROL REGISTER This register controls the CSI2 RECEIVER module. This register must not be modified dynamically (except IF_EN bit field).		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0														
RESERVED																VP_CLK_EN	RESERVED	RESERVED	RESERVED	VP_ONLY_EN	RESERVED	VP_OUT_CTRL	DBG_EN	RESERVED	RESERVED	FRAME	ECC_EN	RESERVED	IF_EN																

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0000
15	VP_CLK_EN	VP clock enable. 0x0: The VP clock is disabled. 0x1: The VP clock is enabled.	RW	0x0
14	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
13	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
12	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
11	VP_ONLY_EN	VP only enable. 0x0: The VP is enabled and the OCP master port is enabled. 0x1: The VP is enabled and the OCP master port is disabled.	RW	0x0
10	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0

Bits	Field Name	Description	Type	Reset
9:8	VP_OUT_CTRL	Video port output clock control. Sets the video port output clock as a function of the interface clock (OCPCLK).  0x0: No division: video port clock = OCPCLK. 0x1: Division by 2: video port clock = OCPCLK/2. 0x2: Division by 3: video port clock = OCPCLK/3. 0x3: Division by 4: video port clock = OCPCLK/4.	RW	0x1
7	DBG_EN	Enables the debug mode.  0x0: Disable 0x1: Enable	RW	0x0
6:5	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
4	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
3	FRAME	Set the modality in which IF_EN works.  0x0: If IF_EN = 0 the interface is disabled immediately. 0x1: If IF_EN = 1 the interface is disabled after all FEC sync code have been received for the active contexts.	RW	0x0
2	ECC_EN	Enables the Error Correction Code check for the received header (short and long packets for all virtual channel ids).  0x0: Disabled 0x1: Enabled	RW	0x0
1	RESERVED	RESERVED	RW	0x0
0	IF_EN	Enables the physical interface to the module.  0x0: The interface is disabled. If FRAME = 0, it is disabled immediately. If FRAME = 1, it is disabled when each context has received the FEC sync code.  0x1: The interface is enabled immediately, the data acquisition starts on the next FSC sync code. Writing 1 to this register when the current value is 0 has the effect to clear the output FIFO. The pixel data of the following frame are written in the PING buffer, that is, the <a href="#">CSI2_CTx_CTRL1</a> .PING_PONG bits are reset to 0 as well.	RW	0x0

<b>Description</b>	COMPLEXIO CONFIGURATION REGISTER for the complex I/O #1 This register contains the lane configuration for the order and position of the lanes (clock and data) and the polarity order for the control of the PHY differential signals in addition to the control bit for the power FSM.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED	RESERVED	RESET_DONE	PWR_CMD	PWR_STATUS	PWR_AUTO	RESERVED										DATA2_POL	DATA2_POSITION	DATA1_POL	DATA1_POSITION	CLOCK_POL	CLOCK_POSITION										

Bits	Field Name	Description	Type	Reset
31:30	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
29	RESET_DONE	Internal reset monitoring of the power domain using the PPI byte clock from the complex io 0x0: Internal module reset is on going. 0x1: Reset completed.	R	0x0
28:27	PWR_CMD	Command for power control of the complex io 0x0: Command to change to OFF state 0x1: Command to change to ON state 0x2: Command to change to Ultra Low Power state	RW	0x0
26:25	PWR_STATUS	Status of the power control of the complex io 0x0: Complex I/O in OFF state 0x1: Complex I/O in ON state 0x2: Complex I/O in ultra-low power state	R	0x0
24	PWR_AUTO	Automatic switch between ULP and ON states based on ULPM signals from complex I/O 0x0: Disable 0x1: Enable	RW	0x0
23:12	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
11	DATA2_POL	+/- differential pin order of DATA lane 2. 0x0: +/- pin order (csi2_dx=+ and csi2_dy=-) 0x1: -/+ pin order (csi2_dx=- and csi2_dy=+)	RW	0x0
10:8	DATA2_POSITION	Position and order of the DATA lane 2. 0x0: Not used/connected 0x1: Data lane 2 is at the position 1. 0x2: Data lane 2 is at the position 2. 0x3: Data lane 2 is at the position 3.	RW	0x0

Bits	Field Name	Description	Type	Reset
7	DATA1_POL	+/- differential pin order of DATA lane 1. 0x0: +/- pin order (csi2_dx=+ and csi2_dy=-) 0x1: -/+ pin order (csi2_dx=- and csi2_dy=+)	RW	0x0
6:4	DATA1_POSITION	Position and order of the DATA lane 1. The data lane 1 is always present. 0x0: Not used/connected. 0x1: Data lane 1 is at the position 1. 0x2: Data lane 1 is at the position 2. 0x3: Data lane 1 is at the position 3.	RW	0x0
3	CLOCK_POL	+/- differential pin order of CLOCK lane. 0x0: +/- pin order (csi2_dx=+ and csi2_dy=-) 0x1: -/+ pin order (csi2_dx=- and csi2_dy=+)	RW	0x0
2:0	CLOCK_POSITION	Position and order of the CLOCK lane. The clock lane is always present. 0x0: Not used/connected. 0x1: Clock lane is at the position 1. 0x2: Clock lane is at the position 2. 0x3: Clock lane is at the position 3.	RW	0x0

<b>Address Offset</b>	0x0000 0070 + (x*0x20)	<b>Index</b>	x = 0 to 7
<b>Physical Address</b>	0x480B D870 + (x*0x20) 0x480B D870 + (x*0x20)	<b>Instance</b>	ISP ISP_CSI2A
<b>Description</b>	CONTROL REGISTER - Context This register controls the Context. This register is shadowed: modifications are taken into account after the next FSC sync code.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								FEC_NUMBER								COUNT								EOF_EN	EOL_EN	CS_EN	COUNT_UNLOCK	PING_PONG	RESERVED	LINE_MODULO	CTX_EN

Bits	Field Name	Description	Type	Reset
31:24	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x00
23:16	FEC_NUMBER	Number of FEC to receive between using swap of <a href="#">CSI2_CTX_DAT_PING_ADDR</a> and <a href="#">CSI2_CTX_DAT_PONG_ADDR</a> for the calculation of the address in memory. (must be used only in interlace mode, otherwise set to 1)	RW	0x01
15:8	COUNT	Sets the number of frame to acquire. Once the frame acquisition starts, the COUNT value is decremented after every frame. When COUNT reaches 0, the FRAME_NUMBER_IRQ interrupt is triggered and CTX_EN is set to 0. Writes to this bit field are controlled by the COUNT_UNLOCK bit. During the same OCP write access , the bit-field COUNT_UNLOCK must be written in addition to COUNT bit-field to change the COUNT value. COUNT can be overwritten dynamically with a new count value." 0: Infinite number of frames (no count). 1: 1 frame to acquire ... 255: 255 frames to acquire.	RW	0x00
7	EOF_EN	Indicates if the end of frame signal must be asserted at the end of the frame. 0x0: The end of frame signal is not asserted at the end of each frame. 0x1: The end of frame signal is asserted at the end of each frame.	RW	0x0
6	EOL_EN	Indicates if the end of line signal must be asserted at the end of the line. 0x0: The end of line signal is not asserted at the end of each line. 0x1: The end of line signal is asserted at the end of each line.	RW	0x0
5	CS_EN	Enables the checksum check for the received payload (long packet only). 0x0: Disabled 0x1: Enabled	RW	0x0
4	COUNT_UNLOCK	Unlock writes to the COUNT bit field. 0x0: COUNT bit field is locked. Writes have no effect 0x1: COUNT bit field is unlocked. Writes are possible.	W	0x0

Bits	Field Name	Description	Type	Reset
3	PING_PONG	Indicates whether the PING or PONG destination address ( <a href="#">CSI2_CTx_DAT_PING_ADDR</a> or <a href="#">CSI2_CTx_DAT_PONG_ADDR</a> ) was used to write the last frame. This bit field toggles after every FEC sync code received for the current context.  0x0: PING buffer 0x1: PONG buffer	R	0x1
2	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
1	LINE_MODULO	Line modulo configuration  0x0: <a href="#">CSI2_CTx_CTRL3.LINE_NUMBER</a> is used once per frame for the generation of the <a href="#">LINE_NUMBER_IRQ</a> .  0x1: <a href="#">CSI2_CTx_CTRL3.LINE_NUMBER</a> is used as a modulo number for the generation of the <a href="#">LINE_NUMBER_IRQ</a> (multiple times the interrupt can be generated for each frame)	RW	0x0
0	CTX_EN	Enables the Context  0x0: Disabled 0x1: Enabled	RW	0x0

**Table 12-649. CSI2\_CTLx\_DAT\_OFST**

<b>Address Offset</b>	0x0000 0078 + (x*0x20)	<b>Index</b>	x = 0 to 7
<b>Physical Address</b>	0x480B D878 + (x*0x20) 0x480B D878 + (x*0x20)	<b>Instance</b>	ISP ISP_CSI2A
<b>Description</b>	DATA MEM ADDRESS OFFSET REGISTER - Context This register sets the offset, which is applied on the destination address after each line is written to memory. This register applies for both <a href="#">CSI2_CTLx_DAT_PING_ADDR</a> and <a href="#">CSI2_CTLx_DAT_PONG_ADDR</a> . For example, it enables to perform 2D data transfers of the pixel data into a frame buffer. In such case, the pixel data and frame buffer data must have the same data format. Note that the 5 LSBs are ignored: the offset must be a multiple of 32 bytes. This register is shadowed: modifications are taken into account after the next FSC sync code. Only full 32-bit values must be written.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								OFST								RESERVED															

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0000
15:5	OFST	Line offset programmed in bytes (signed value 2's complement). If OFST = 0, the data is written contiguously in memory. Otherwise, OFST sets the destination offset between the first pixel of the previous line and the first pixel of the current line.	RW	0x000
4:0	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x00

<b>Physical Address</b>	0x480B D87C + (x*0x20) 0x480B D87C + (x*0x20)	<b>Instance</b>	ISP ISP_CSI2A
<b>Description</b>	DATA MEM PING ADDRESS REGISTER - Context This register sets the 32-bit memory address where the pixel data are stored. The destination is double buffered: this register sets the PING address. Double buffering is enabled when the addresses <a href="#">CSI2_CT<sub>x</sub>_DAT_PING_ADDR</a> and <a href="#">CSI2_CT<sub>x</sub>_DAT_PONG_ADDR</a> are different. Note that the 5 LSBs are ignored: the address should be aligned on a 32-byte boundary. This register is shadowed: modifications are taken into account after the next FSC sync code. Only full 32-bit values must be written.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

<b>13.1 SGX Overview .....</b>	<b>1753</b>
<b>13.2 SGX Integration .....</b>	<b>1756</b>
<b>13.3 SGX Functional Description .....</b>	<b>1758</b>
<b>13.4 SGX Register Mapping .....</b>	<b>1759</b>

## 13.1 SGX Overview

The 2D/3D graphics accelerator (SGX) subsystem accelerates 2-dimensional (2D) and 3-dimensional (3D) graphics applications. The SGX subsystem is based on the POWERVR™ SGX core from Imagination Technologies. SGX is a new generation of programmable POWERVR graphic cores. The POWERVR™ SGX530 v1.2.1 architecture is scalable and can target all market segments from mainstream mobile devices to high-end desktop graphics. Targeted applications include feature phone, PDA, and hand-held games.

Figure 13-1 shows the SGX subsystem in the device.

**Figure 13-1. Graphics Accelerator Highlight**

sgx-001

The SGX graphics accelerator efficiently processes a number of various multimedia data types concurrently:

- Pixel data
- Vertex data
- Video data
- General-purpose processing

This is achieved using a multithreaded architecture using two levels of scheduling and data partitioning enabling zero overhead task switching.

The SGX subsystem is connected by a 64-bit master and a 32-bit slave interface to the L3 interconnect.

### 13.1.1 POWERVR SGX Main Features

- 2D graphics, 3D graphics, vector graphics, and programming support for GP-GPU functions
- Tile-based architecture
- USSE™ – multithreaded engine incorporating pixel and vertex shader functionality

- Advanced shader feature set – in excess of Microsoft VS3.0, PS3.0, and OpenGL2.0
- Industry standard API support – Direct3D Mobile, OpenGL ES 1.1 and 2.0, OpenVG v1.0.1
- Fine-grained task switching, load balancing, and power management
- Advanced geometry direct memory access (DMA) driven operation for minimum CPU interaction
- Programmable high-quality image anti-aliasing
- POWERVR SGX core MMU for address translation from the core virtual address to the external physical address (up to 4GB address range)
- Fully virtualised memory addressing for OS operation in a unified memory architecture
- Advanced and standard 2D operations [e.g., vector graphics, BLTs (block level transfers), ROPs (raster operations)]

### 13.1.2 SGX 3D Features

- Deferred pixel shading
- On-chip tile floating point depth buffer
- 8-bit stencil with on-chip tile stencil buffer
- 8 parallel depth/stencil tests per clock
- Scissor test
- Texture support:
  - Cube map
  - Projected textures
  - 2D textures
  - Nonsquare textures
- Texture formats:
  - RGBA 8888, 565, 1555
  - Monochromatic 8, 16, 16f, 32f, 32int
  - Dual channel, 8:8, 16:16, 16f:16f
  - Compressed textures PVR-TC1, PVR-TC2, ETC1
  - Programmable support for all YUV formats
- Resolution support:
  - Frame buffer maximum size = 2048 x 2048
  - Texture maximum size = 2048 x 2048
- Texture filtering:
  - Bilinear, trilinear
  - Independent minimum and maximum control
- Antialiasing:
  - 4x multisampling
  - Up to 16x full scene anti-aliasing
  - Programmable sample positions
- Indexed primitive list support
  - Bus mastered
- Programmable vertex DMA
- Render to texture:
  - Including twiddled formats
  - Auto MipMap generation
- Multiple on-chip render targets (MRT).  
**Note:** Performance is limited when the on-chip memory is not available.

### 13.1.3 Universal Scalable Shader Engine (USSE) – Key Features

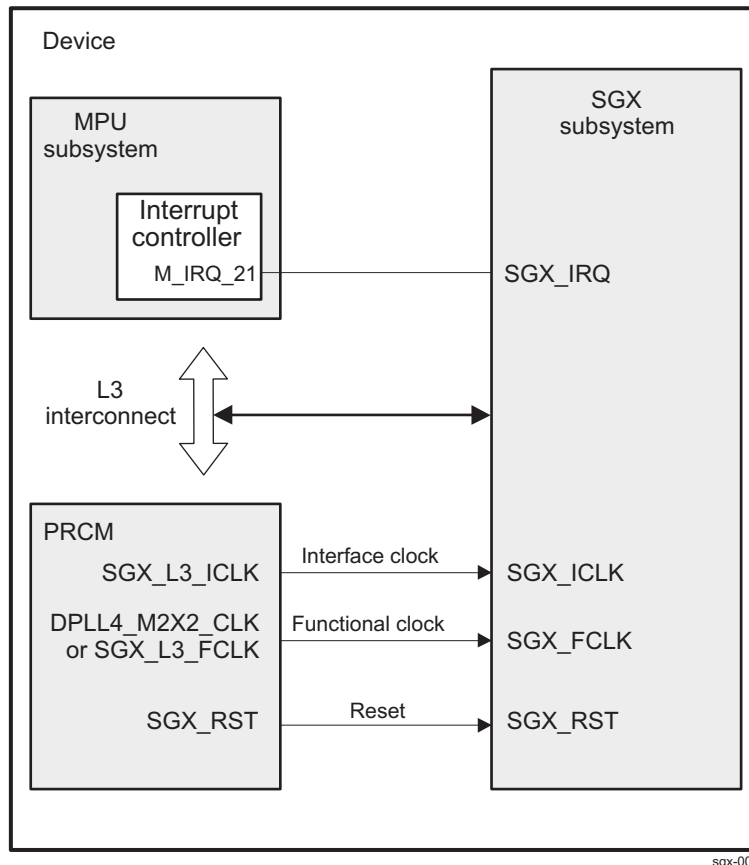

The USSE is the engine core of the POWERVR SGX architecture and supports a broad range of instructions.

- Single programming model:
  - Multithreaded with 16 simultaneous execution threads and up to 64 simultaneous data instances
  - Zero-cost swapping in, and out, of threads
  - Cached program execution model
  - Dedicated pixel processing instructions
  - Dedicated video encode/decode instructions
- SIMD execution unit supporting operations in:
  - 32-bit IEEE float
  - 2-way 16-bit fixed point
  - 4-way 8-bit integer
  - 32-bit bit-wise (logical only)
- Static and dynamic flow control:
  - Subroutine calls
  - Loops
  - Conditional branches
  - Zero-cost instruction predication
- Procedural geometry:
  - Allows generation of primitives
  - Effective geometry compression
  - High-order surface support
- External data access:
  - Permits reads from main memory using cache
  - Permits writes to main memory
  - Data fence facility
  - Dependent texture reads

## 13.2 SGX Integration

Figure 13-2 highlights the SGX subsystem integration in the device.

**Figure 13-2. SGX Subsystem Integration**

### 13.2.1 Clocking, Reset, and Power-Management Scheme

#### 13.2.1.1 Clocks

The SGX subsystem operates from two clocks: an interface clock (SGX\_ICLK) and a functional clock (SGX\_FCLK). The power, reset, and clock management (PRCM) module generates and distributes both clocks inside the device. The SGX clock tree is depicted in [Figure 4-44, SGX Power Domain Clocking Scheme](#), in [Chapter 4, Power, Reset, and Clock Management](#).

**Table 13-1. Clock Descriptions**

Signal Name	I/O <sup>(1)</sup>	Description
SGX_FCLK	I	Functional clock (two possible clock sources) -> Functional clock domain
SGX_ICLK	I	Interface clock (L3 interconnect clock domain) -> Interface clock domain

<sup>(1)</sup> I=Input, O=Output,

- The SGX\_ICLK interface clock manages the data transfer on the L3 master and slave ports. The source of SGX\_ICLK is the PRCM clock (SGX\_L3\_ICLK), which belongs to the SGX clock domain and runs at the L3 interconnect clock speed. The SGX\_ICLK frequency is selected based on the whole device L3 interconnect clock frequency. For more information on the interface clock, see [Chapter 4, Power, Reset, and Clock Management](#).

When no longer required by the SGX subsystem, SGX\_ICLK can be disabled by software at the PRCM level by setting the PRCM.CM\_ICLKEN\_SGX[0] EN\_SGX bit to 0. For more information, see

Figure 4-60, *SGX Power Domain Clock Controls*, in [Chapter 4, Power, Reset, and Clock Management](#).

**NOTE:** SGX\_ICLK is cut only if the SGX is ready to go into idle state. For more information, see [Chapter 4, Power, Reset, and Clock Management](#).

- SGX\_FCLK is the functional clock and is used inside the SGX subsystem to generate SGX 2D and 3D domain clock signals.

The source of SGX\_FCLK is either the PRCM clock (SGX\_L3\_FCLK, which is derived from SGX\_ICLK) or the peripheral DPLL clock DPLL4\_M2X2\_CLK as depicted in [Figure 4-60, SGX Power Domain Clock Controls](#). Selection is made at the PRCM level by setting the PRCM.CM\_CLKSEL\_SGX[2:0] CLKSEL\_SGX bit field. A divider of 3, 4, or 6 is applied to the SGX\_FCLK frequency with regard to the PRCM SGX\_L3\_FCLK frequency. By default the SGX\_FCLK clock is SGX\_L3\_FCLK / 3.

Whether SGX\_FCLK is provided by SGX\_L3\_FCLK or DPLL4\_M2X2\_CLK, its gating depends on the PRCM.CM\_FCLKEN\_SGX[1] EN\_SGX bit. Clearing this bit to 0 indicates that both SGX clocks are no longer needed and can be cut at the PRCM level, if the module is ready to enter the idle state. For more information, see [Section 4.5.5.8, SGX Power Domain](#), in [Chapter 4, Power, Reset, and Clock Management](#)

### 13.2.1.2 Resets

The SGX subsystem has its own reset domain. Global reset of the SGX is performed by activating the SGX\_RST signal in the SGX\_RST domain. Software controls the release of SGX\_RST using the PRCM.RM\_RSTCTRL\_SGX[0] SGX\_RST bit.

### 13.2.1.3 Power Management

The SGX subsystem has its own power domain (SGX power domain). See [Chapter 4, Power, Reset, and Clock Management](#), for additional information about the SGX power domain.

As described in [Section 13.2, SGX Integration](#), the SGX subsystem receives two clock signals from the PRCM module. The functional clock is either a division of the interface clock with a ratio of 1:3, 1:4, or 1:6, or a 96-MHz clock issued from a DPLL4. The functional clock is used inside the SGX to generate clock signals to the multiple internal module SGX clock domains. The division ratio depends on the PRCM registers setting. For more information, see [Chapter 4, Power, Reset, and Clock Management](#).

Three power-management modes are defined:

- Deep power sleep (All clocks are gated.)
- Idle (2D and 3D clocks are gated.)
- 3D (No clock is gated.)

The SGX handles the automatic clock gating performed on the multiple internal module clock domains.

## 13.2.2 Hardware Requests

### 13.2.2.1 Interrupt Request

The SGX subsystem can generate one interrupt (SGX\_IRQ) to the MPU subsystem interrupt controller mapped on M\_IRQ\_21.

## 13.3 SGX Functional Description

### 13.3.1 SGX Block Diagram

The SGX subsystem is based on the POWERVR SGX530 core from Imagination Technologies. The architecture uses both programmable and hard coded pipelines to perform various processing tasks required in 2D, 3D, and video processing. The SGX architecture comprises the following elements:

- Coarse grain scheduler
  - Programmable Data Sequencer (PDS)
  - Data Master Selector (DMS)
- Vertex data master (VDM)
- Pixel data master (PDM)
- General-purpose data master
- USSE
- Tiling coprocessor
- Pixel coprocessor
- Texturing coprocessor
- Multilevel cache

Figure 13-3 shows a block diagram of the SGX cores.

**Figure 13-3. SGX Block Diagram**

sgx-003

### 13.3.2 SGX Elements Description

The coarse grain scheduler (CGS) is the main system controller for the POWERVR SGX Architecture. It consists of two stages, the DMS and the PDS. The DMS processes requests from the data masters and determines which tasks can be executed given the resource requirements. The PDS then controls the loading and processing of data on the USSE.

There are three data masters in the SGX core:

- The VDM is the initiator of transform and lighting processing within the system. The VDM reads an

input control stream, which contains triangle index data, and state data. The state data indicates the PDS program, size of the vertices and the amount of USSE output buffer resource available to the VDM. The triangle data is parsed to determine unique indices that must be processed by the USSE. These are grouped together according to the configuration provided by the driver and presented to the DMS.

- The PDM is the initiator of rasterization processing within the system. Each pixel pipeline processes pixels for a different half of a given tile which allows for optimum efficiency within each pipe due to locality of data. For each task it determines the amount of resource required within the USSE. It merges this with the state address and issues a request for execution on the USSE to the DMS.
- The general-purpose data master responds to events within the system (such as end of a pass of triangles from the ISP, end of a tile from the ISP, end of render, or parameter stream breakpoint event). Each event causes either an interrupt to the host or synchronized execution of a program on the PDS. The program may, or may not cause a subsequent task to be executed on the USSE.

The USSE is a user-programmable processing unit. Although general in nature, its instructions and features are optimized for three types of task: processing vertices (vertex shading), processing pixels (pixel shading), and video/imaging processing.

The multilevel cache is a 2-level cache consisting of two modules: the main cache and the mux/arbiter/demux/decompression unit (MADD). The MADD is a wrapper around the main cache module designed to manage and format requests to and from the cache, as well as providing Level 0 caching for texture and USSE requests. The MADD can accept requests from the PDS, USSE, and texture address generator modules. Arbitration is performed between the three data streams; any required texture decompression is also performed.

The texturing coprocessor performs texture address generation and formatting of texture data. It receives requests from either the iterators or USSE modules and translates these into requests into the multilevel cache. Data returned from the cache are then formatted according to the texture format selected and sent to the USSE for pixel-shading operations.

To process pixels in a tiled manner, the screen is divided into tiles and arranged as groups of tiles by the tiling coprocessor. An inherent advantage of tiling architecture is that a large amount of vertex data can be rejected at this stage, thus reducing both the memory storage requirements and the amount of pixel processing to be performed.

The pixel coprocessor is the final stage of the pixel-processing pipeline and controls the format of the final pixel data sent to the memory. It supplies the USSE with an address into the output buffer, and the USSE returns the relevant pixel data. The address order is determined by the frame buffer mode. The pixel coprocessor contains a dithering and packing function.

## 13.4 SGX Register Mapping

[Table 13-2](#) describes the SGX memory mapping in the device.

**Table 13-2. Instance Summary**

Module Name	Start Address	End Address	Size
SGX	0x5000 0000	0x5000 FFFF	64K bytes

### CAUTION

The SGX registers are limited to 32-bit data accesses; 8- and 16-bit accesses are not allowed because they can corrupt register content.

## IVA2.2 Subsystem

---

---

---

This chapter describes the image video and audio accelerator (IVA2.2) subsystem.

---

**NOTE:** Some features may not be available or supported in your particular device. For more information, see Chapter 1, the Device Family section, and your device-specific data manual.

## 14.1 IVA2.2 Subsystem Overview

The device includes the high-performance Texas Instruments image video and audio accelerator (IVA2.2), based on the TMS320DMC64X+ VLIW digital signal processor (DSP) core.

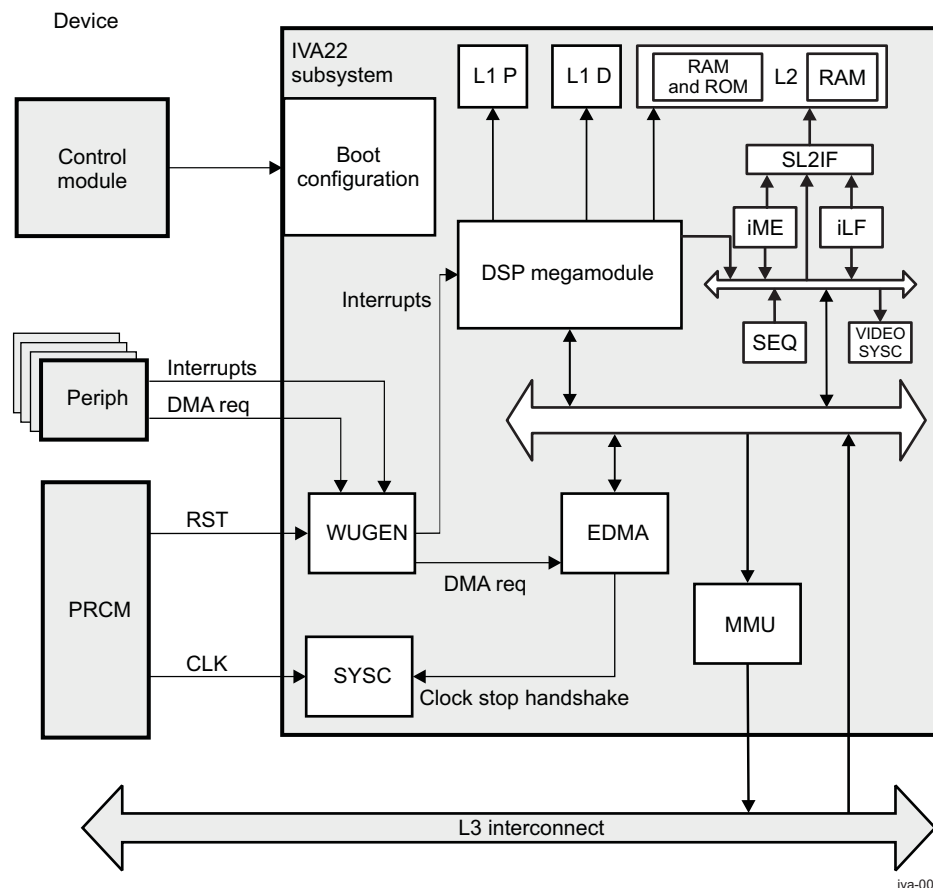

The internal architecture is an assembly of the following components:

- High-performance TI DSP (TMS320DMC64X+) integrated in a megamodule, including local L1/L2 cache and memory controllers
- L1 RAM and L2 RAM and ROM
- Video hardware accelerator module, including local sequencer
- Dedicated enhanced data memory access (EDMA) engine to download/upload data from/to memories and peripherals external to the subchip
- Dedicated memory management unit (MMU) for accessing level 3 (L3) interconnect address space
- Local interconnect network
- Dedicated modules SYSC and WUGEN in charge of power management, clock generation, and connection to the power, reset, and clock manager (PRCM) module

For information about C64x to C64x+ core migration see external document [Section 14.3.1.8](#).

Figure 14-1 shows the IVA2.2 subsystem top-level architecture.

Figure 14-1. IVA2.2 Subsystem Highlight

### 14.1.1 IVA2.2 Subsystem Key Features

The IVA2.2 subsystem has the following main features:

- 32-bit fixed-point media processor
- VLIW architecture based on programmable enhanced version of C64x DSP core

- 8 instructions/cycle, 8 execution units:
  - Optimized instruction set for video and image processing
  - Eight 8 x 8 or 16 x 16 MAC per cycle
  - Eight SAD per cycle
  - Eight interpolations (a + b + 1) >>1 per cycle
  - Two (32-bit x 32-bit > 64-bit) multiply operations per cycle
- Low-power processor and megamodule:
  - Dynamically mixed 32-bit and 16-bit instruction sets
  - Software pipelined loop (SPLOOP) instruction buffer
  - Separate power domain
  - Supported multiple power-down states
- 2-level memory subsystem hierarchy:
  - L1P (program):
    - 32KB direct-mapped cache-32-byte cache line, configurable as cache or memory-mapped (possible values are: 0KB cache/32KB memory, 4KB/28KB, 8KB/24KB, 16KB/16KB, or 32KB/0KB)
  - L1D (data):
    - 32KB 2-way set associative cache-64-byte cache line, configurable as cache or memory-mapped (possible values are: 0KB cache/32KB memory, 4KB/28KB, 8KB/24KB, 16KB/16KB, or 32KB/0KB)
    - 48-KB memory-mapped SRAM
  - L2 (program and data):
    - 64KB 2-way set associative cache-128-byte cache line, configurable as cache or memory-mapped (possible values are: 0KB cache/64KB memory, 32KB/32KB, or 64KB/0KB)
    - 32-KB memory-mapped SRAM
    - 16-KB ROM
- Video hardware accelerator:
  - Improved motion estimation dedicated hardware
  - Improved loop-filtering dedicated hardware
  - Dedicated sequencer
  - Local interconnect
  - Shared level 2 (L2) memory interface/arbiter
- Private direct memory access (DMA) controller:
  - 128 logical channels
  - 1D/2D addressing
  - Chaining capability
  - Fully pipelined, two 64-bit read ports, two 64-bit write ports
  - Single-access 32-byte or 64-byte incrementing bursts
- Level 1 (L1) interrupt controller
- Local IVA digital phase-locked loop (DPLL) supplying IVA subsystem clocking
- 32-entry MMU for seamless integration in high-level operating system (OS) environment
- IVA2.2 system interfaces:
  - 64-bit L3 port shared for external memory accesses:
    - Multithreaded link shared by DSP core and DMA accesses
    - Interface with the L3 interconnect that can be synchronous or asynchronous for clock decoupling between IVA2.2 and L3
    - Incrementing burst support

- Critical line first, to reduce line-fetch latency to the processor
- Host port interface (HPI) for MMU programming and access to IVA2.2 internal memories. Can be synchronous or asynchronous.
- System interfaces: clocking, power management
- C-friendly environment (state-of-the-art C-compiler for VLIW architecture)
- Texas Instruments low-overhead DSP-BIOS operating system

## 14.2 IVA2.2 Subsystem Integration

[Figure 14-2](#) shows IVA2.2 subsystem integration in the device.

Figure 14-2. IVA2.2 Subsystem Integration

iva-002

## 14.2.1 Clocking, Reset, and Power-Management Scheme

### 14.2.1.1 Clocks

#### 14.2.1.1.1 IVA2.2 Clocks

The IVA2.2 subsystem receives one single clock signal (IVA\_CLK) from the PRCM.

---

**NOTE:** When the IVA2.2 subsystem does not require an internal clock, the internal clocks can be disabled at the PRCM level by setting the PRCM.CM\_FCLKEN\_IVA2 EN\_IVA2 bit to 0.

---

From this clock (IVA\_CLK), three internal clocks are generated by the IVA2.2 system control module (SYSC):

- CD0\_CLK: Fastest IVA2.2 subsystem functional clock, dedicated to the DSP. Its frequency can be adjusted at the PRCM level by setting the PRCM.CM\_CLKSEL1\_PLL\_IVA2 and PRCM.CM\_CLKSEL2\_PLL\_IVA2 registers.
- CD1\_CLK: Divide-by-two of the CD0\_CLK clock
- CD2\_CLK: Divide-by-two of the CD0\_CLK clock

Generation of these three clocks is handled internally to the IVA2.2 subsystem by the SYSC module under direct control of the PRCM.

Table 14-1 lists the clock domains in the IVA2.2 subsystem and shows the roles of the clocks.

**Table 14-1. IVA2.2 Internal Clock**

<b>CD0</b>	CD0_CLK	DSP core + PMC + DMC
<b>CD1</b>	CD1_CLK	UMC + power-down + interrupt controller
<b>CD2</b>	CD2_CLK	EMC + IDMA + DSP megamodule external interfaces + local interconnect + EDMA + MMU + SYSC + iME + iLF

---

**NOTE:** The internal clocks can be shut down by the PRCM module after the handshake protocol is complete. To configure the PRCM so that internal clocks are hardware-supervised, set the PRCM.CM\_AUTOIDLE\_PLL\_IVA2[2:0] AUTO\_IVA2\_DPLL field to 0x1. For more information, see [Chapter 4, Power, Reset, and Clock Management](#).

---

The video sequencer module receives SEQ\_CLK from CD2\_CLK. This divided clock is generated in the video accelerator/sequencer system configuration. For more information about the divided clock of the sequencer, see [Section 14.4.9.1, Clock Management](#).

#### **CAUTION**

Clock configurations depend on core voltage, and maximum clock frequencies may not apply to production.

### 14.2.1.2 Resets

#### 14.2.1.2.1 Hardware Resets

Figure 14-3 shows the seven hardware input reset signals at the boundary of the IVA2.2 subsystem:

- IVA2\_RST1, connected to the DSP megamodule and EDMA modules
- IVA2\_RST2, connected to the SYSC, MMU, iME, iLF, and local interconnect
- IVA2\_RST3, connected to the sequencer
- CORE\_RST, connected to the IVA2.2 subsystem wake-up generator (WUGEN) module

- RET\_RST, connected to the subsystem WUGEN retention logic to reset registers that keep their value across a warm reset sequence
- IVA2\_RSTPWRON, which performs a power-on initialization of IVA2.2 logic

**Figure 14-3. IVA2.2 Subsystem Resets**

After chip power on, the IVA2.2 subsystem is kept under reset and only the RET\_RST is released from reset. Then, only the WUGEN is released from reset as part of the core domain. The IVA2.2 remains under reset until the microprocessor unit (MPU) clears the PRCM.RM\_RSTCTRL\_IVA2[1] RST2\_IVA2 bit. On this action, the PRCM switches on the IVA2.2 power domain, sets the clocks back, and releases the power-on reset. When the IVA2.2 power-on sequence completes (hardware handshake), the PRCM releases the IVA2\_RST2 reset. At this stage, the DSP megamodule is kept under reset (unless the MPU also cleared the PRCM.RM\_RSTCTRL\_IVA2[0] RST1\_IVA2 bit); the MPU can upload some code and data in the C64x+ memory. When the MPU has uploaded the code in the C64x+ memory, the MPU clears the RST1\_IVA2 bit, releasing the DSP megamodule from reset. At this point, the sequencer is kept under reset (unless the PRCM.RM\_RSTCTRL\_IVA2[2] RST3\_IVA2 bit was cleared); the DSP can upload some code and data in the sequencer memory. When the DSP has uploaded the coded in the sequencer memory, the DSP clears the RST3\_IVA2 bit, releasing the sequencer from reset.

The MPU can apply a software reset to the IVA2.2. For a software reset to be safe, the IVA2.2 must be in clock-off mode (DSP in idle mode with clocks shut down by the PRCM; for information about the clock-off state transition, see [Section 14.4.9.3](#), *Power-Down and Wake-Up Management*.) For instance, the MPU can use a mailbox interrupt to ask the IVA2.2 to go to IDLE state. In that case, only IVA2\_RST1 and/or IVA2\_RST2 and/or IVA2\_RST3 are applied, depending on which bits are set, and CORE\_RST and IVA2\_RSTPWRON are never applied.

The IVA2.2 can also program the PRCM to go to OFF state automatically when the IVA2.2 is idle. Then, in response to a wake-up event (for example, an interrupt), the PRCM can switch on the IVA2.2 power domain, set the clocks back, and release the power-on reset. When the IVA2.2 power-on sequence completes (hardware handshake), the PRCM releases the IVA2\_RST3, IVA2\_RST2, and IVA2\_RST1 resets (RST1, RST2, and RST3 SW bits are assumed to be clear). However, for the IDLE instruction (to transition to OFF state) to be executed, the user must program the PRCM to prevent the sequencer (IVA2\_RST3) from being released from reset after a wakeup of the IVA2 from POWER OFF state. CORE\_RST can be applied only if the device is coming out of CHIP OFF state (CORE power domain also in OFF state). In this case, CORE\_RST is released at the same time as the IVA power-on reset.

For some detected severe issues or if the user applies an external system reset, the IVA2.2 can receive a warm reset. IVA2\_RST1, IVA2\_RST2, IVA2\_RST3, DPLL\_RST, RET\_RST, and CORE\_RST are applied. When the warm reset source is released, IVA2\_RST1, IVA2\_RST2, IVA2\_RST3, and CORE\_RST are released. Power-on reset is not applied in this case.

#### 14.2.1.2.2 Software Resets

IVA2.2 subsystem reset signals are sourced from the PRCM module. Some modules of the DSP subsystem can also be reset by software control.

The IVA2\_RST1 signal maps to the PRCM.RM\_RSTCTL\_IVA2 RST1\_IVA2 bit, the IVA2\_RST2 signal maps to the PRCM.RM\_RSTCTL\_IVA2 RST2\_IVA2 bit, and the IVA2\_RST3 signal maps to the PRCM.RM\_RSTCTL\_IVA2 RST3\_IVA2 bit in the PRCM register RM\_RSTCTRL\_IVA2. Writing these three bit fields lets the software reset the IVA2.2 subsystem.

---

**NOTE:** Software reset can be applied only while the IVA2.2 subsystem is in clock-off mode.

---

The WUGEN reset signal (CORE\_RST) is reset with the CORE power domain, which is reset at the occurrence of either global cold or global warm reset events. For more information about global reset sources, see [Chapter 4, Power, Reset, and Clock Management](#).

For more information about software resets, see [Section 14.4.9.2, Reset Management](#).

#### 14.2.1.3 Power Domain

The IVA2.2 subsystem comprises three power domains that can be shared with other subsystems at the chip level (see [Figure 14-4](#)):

- DSP power domain: Everything specified in the IVA2.2 subsystem, except the wake-up generator
- CORE power domain: Includes the WUGEN

**Figure 14-4. IVA2.2 Power Domain**

The DSP power domain can be powered off if the CORE power domain is powered on. The PRCM ensures that the DSP power domain is always powered off when the CORE power domain is powered off.

The CORE power domain includes several other system-level components of the device. The WUGEN module is included in the CORE power domain to enable the powered-off DSP subsystem to be awakened after receiving an interrupt, a DMA request, or an L3 slave port access.

Memory voltage can be reduced locally when memory is not being used, to reduce memory leakage:

- If IVA2.2 is not active, this is controlled by the PRCM.PM\_PWSTCTRL\_IVA2 register by setting the MEMONSTATE and/or MEMRETSTATE bit fields.

For a detailed description of power domains and controls in the device, see [Chapter 4, Power, Reset, and Clock Management](#).

## 14.2.2 Hardware Requests

### 14.2.2.1 DMA Requests

The IVA2.2 subsystem receives 14 DMA requests from specific peripherals, such as the McBSP module and the UART module (see Figure 14-5).

Figure 14-5. IVA2.2 EDMA Requests

iva22-005

For a description of the EDMA controller, see Section 14.3.2.1, EDMA.

Table 14-2 lists EDMA request mappings to the IVA2.2 subsystem EDMA controller.

Table 14-2. IVA2.2 Subsystem EDMA Request Mappings

DMA	Source	Description
D_DMA_0	MCBSP1_DMA_TX	MCBSP module 1 - transmit request
D_DMA_1	MCBSP1_DMA_RX	MCBSP module 1 - receive request
D_DMA_2	MCBSP2_DMA_TX	MCBSP module 2 - transmit request
D_DMA_3	MCBSP2_DMA_RX	MCBSP module 2 - receive request
D_DMA_4	MCBSP3_DMA_TX	MCBSP module 3 - transmit request
D_DMA_5	MCBSP3_DMA_RX	MCBSP module 3 - receive request
D_DMA_6	MCBSP4_DMA_TX	MCBSP module 4 - transmit request

**Table 14-2. IVA2.2 Subsystem EDMA Request Mappings (continued)**

DMA	Source	Description
D_DMA_7	MCBSP4_DMA_RX	MCBSP module 4 - receive request
D_DMA_8	MCBSP5_DMA_TX	MCBSP module 5 - transmit request
D_DMA_9	MCBSP5_DMA_RX	MCBSP module 5 - receive request
D_DMA_10	UART3_DMA_TX	UART module 3 - transmit request
D_DMA_11	UART3_DMA_RX	UART module 3 - receive request
D_DMA_12	Reserved	
D_DMA_13	Reserved	
D_DMA_14	Reserved	
D_DMA_15	Reserved	
D_DMA_16	Reserved	
D_DMA_17	Reserved	
D_DMA_18	Reserved	
D_DMA_19	Reserved	

**NOTE:** All EDMA requests are shared DMA requests; they are also mapped on the system DMA (sDMA). For more information, see [Chapter 9, DMA](#).

For more information about EDMA request management, see [Section 14.4.4.3, Programming an EDMA Transfer](#).

### 14.2.2.2 Interrupt Requests

The IVA2.2 subsystem manages three types of interrupts (see [Figure 14-6](#)):

- Internal interrupts: Requests generated by modules in the IVA2.2 subsystem or in the DSP megamodule included in the IVA2.2 subsystem
- External interrupts: Requests generated by peripherals external to the IVA2.2 subsystem, like SPI, display subsystem, or camera subsystem. Peripherals that generate interrupts at the IVA2.2 level use the IVA2\_IRQ[47:0] input lines of the IVA2.2 subsystem.
- MMU interrupt: The IVA2.2 MMU can generate an interrupt to an external host outside the IVA2.2 subsystem. As shown in [Figure 14-2](#), the interrupt line of the MMU, IVA2\_MMU\_IRQ, is connected to M\_IRQ\_28 of the MPU subsystem interrupt controller.

For more information about the functionality of the IVA2.2 MMU, see [Section 14.3, IVA2.2 Subsystem Functional Description](#).

To manage and expand the interrupt capabilities of the DSP megamodule (internal and external interrupt requests), the IVA2.2 subsystem includes two levels of interrupt control (see [Figure 14-6](#)):

- One interrupt controller (INTC), integrated in the DSP megamodule. This module controls all interrupt requests (internal and external) except the MMU interrupt.  
For more information about the INTC, see [Section 14.3.1.7](#).
- One WUGEN: Responsible at the IVA2.2 subsystem level for detecting wake-up events (interrupts, DMA requests, and slave port access) when the IVA2.2 is powered down. The WUGEN also handles formatting interrupts from device peripherals to the DSP megamodule INTC.

Figure 14-6. IVA2.2 Interrupt Management

iva-006

In addition to interrupt sources internal to the IVA2.2 subsystem, several interrupt sources coming from device peripherals are connected to the DSP megamodule INTC, but not directly.

These external interrupt sources are first resynchronized in the WUGEN module, synchronously with the CD2 clock domain clock (CD2\_CLK). Then the resynchronized versions are connected to the INTC.

Table 14-3 lists the global interrupt mappings of the IVA2.2 subsystem.

Table 14-3. IVA2.2 Interrupt Mappings

EVT	Interrupts/Events	IVA2.2 Pin Name	Interrupt Source	Interrupt Description
0	EVT0	N/A (internal)	DSP INT CTL	Output of event combiner 0, for events 4-31
1	EVT1	N/A (internal)	DSP INT CTL	Output of event combiner 1, for events 32-63
2	EVT2	N/A (internal)	DSP INT CTL	Output of event combiner 2, for events 64-95
3	EVT3	N/A (internal)	DSP INT CTL	Output of event combiner 3, for events 96-127
4-8	Reserved	N/A (internal)	N/A	N/A
9	EMU_DTDMA	N/A (internal)	DSP ECM	ECM interrupt (host scan access, DTDMA)
10	Reserved	N/A (internal)	N/A	N/A

126	EMC_CMPA	N/A (internal)	DSP EMC	CPU memory protection fault
127	EMC_BUSERR	N/A (internal)	DSP EMC	BUSERR interrupt

<sup>(1)</sup> EVT94 is used by the DSP to generate an interrupt to the sequencer by means of the HOST\_MBX in the SEQ\_IRQSTATE register.

The interrupts generated by the WUGEN module (interrupts from device peripherals) are programmable using a set of registers accessible by the user.

Events related to these external interrupts can be masked by writing to the IVA2.WUGEN\_MEVTSET0 or IVA2.WUGEN\_MEVTSET1 registers. The interrupts can also be individually unmasked by using the IVA2.WUGEN\_MEVTCLR0 or IVA2.WUGEN\_MEVTCLR1 registers. By default (after power on), these external interrupts are masked in WUGEN.

All other interrupts are directly managed by the IVA2.2 DSP INTC, and the DSP registers are set. For information about the DSP INTC, see the documents listed in [Section 14.3.1.8, Other DSP Reference Documents](#).

### 14.3 IVA2.2 Subsystem Functional Description

The IVA2.2 subsystem is composed of a DSP megamodule coupled with several submodules that enable its integration in the device architecture. The IVA2.2 subsystem provides one slave port and one master port; both ports are connected to the L3 interconnect.

Figure 14-7 is a block diagram of the IVA2.2 subsystem.

Figure 14-7. IVA2.2 Subsystem Block Diagram

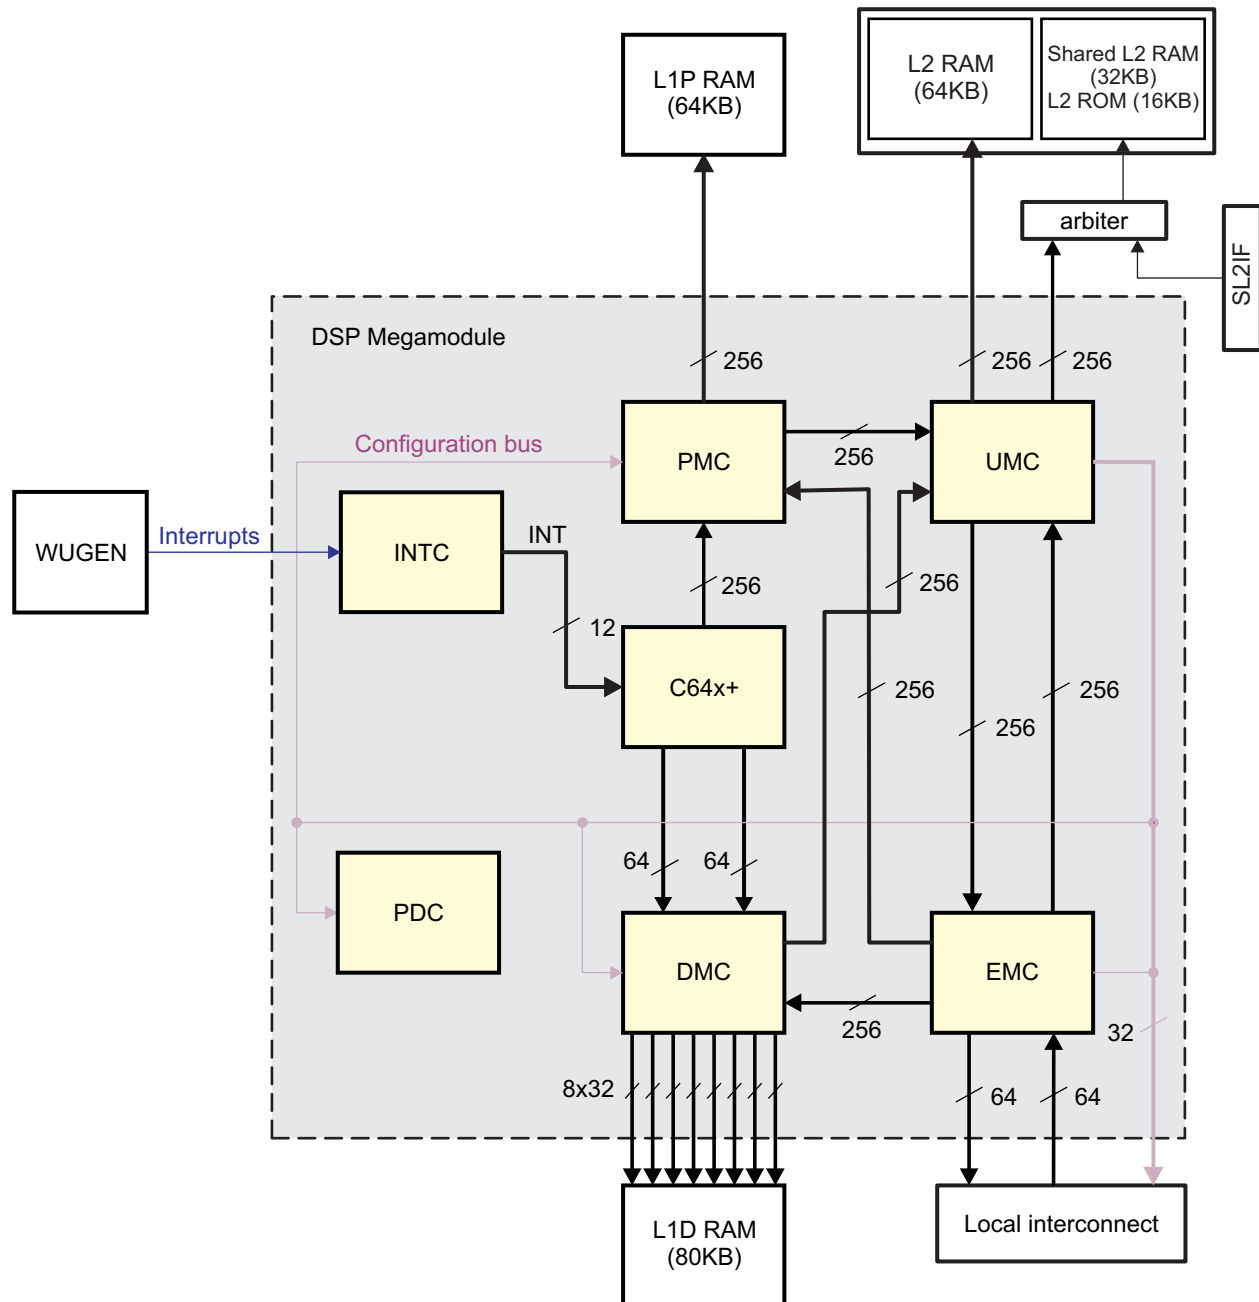

NOTE: This indicates the number of threads for IVA2.2 master/slave port interrupts. For details, see Chapter 5, Interconnect.

### 14.3.1 DSP Megamodule

The C64x+ DSP megamodule is a class of derivative sections of the generalized embedded megamodule. DSP megamodule is a hardware-configurable megamodule module that comprises a version of the C64x+, an L1 program memory controller (PMC), an L1 data memory controller (DMC), a unified memory controller (UMC), an extended memory controller (EMC), an INTC, and a power-down controller (PDC).

Figure 14-8 is a block diagram of the DSP megamodule.

Figure 14-8. DSP Megamodule Block Diagram

iva22-108

### 14.3.1.1 DSP Overview

The C64x+ is an extension of the first C64x DSP section (also named Kelvin).

The C64x features the following:

- 32-bit fixed-point media processor
- VLIW architecture
- 8 instructions/cycle, 8 execution units
  - Optimized instruction set for video and image processing
  - Eight 8 x 8 or 16 x 16 MAC per cycle

- Eight SAD per cycle
- Eight interpolations  $(a + b + 1) \gg 1$  per cycle
- Two (32-bit x 32-bit > 64-bit) multiply operations per cycle

In addition to existing C64x features, the C64x+ includes the following:

- SPLOOP
- Compact instructions
- Extended function support
- Exception handling
- Privilege mode support
- HLOS time-stamp counter register

#### CAUTION

Clock configurations depend on core voltage, and maximum clock frequencies may not apply to production.

For information about C64x+ DSP, see the C64x+ reference manual ([Section 14.3.1.8](#)).

#### 14.3.1.2 Program Memory Controller Overview

The PMC is the DSP megamodule component that delivers program fetch packets when they are requested by the DSP.

The PMC supports the following features:

- One 256-bit fetch packet per cycle (sustainable)
- 32KB 0-wait state least-significant bit (LSB)-banked SRAM
- L1 program cache controller - 32KB maximum
- Software-programmable allocation of SRAM to cache or memory-mapped SRAM
- DMA transfer from/to SRAM
- Fair priority-based arbitration between DSP, DMA, and cache controller for access to the SRAM
- Block and global program-initiated cache coherence support (invalidate)
- Freeze mode support

In the IVA2.2 subsystem, the PMC controls the 32-KB SRAM typically used as cache RAM. However, the allocation of SRAM can be software-configured to keep a section of the memory as memory-mapped SRAM.

For more information, see [Section 14.4.8](#), *Memory Management*.

#### 14.3.1.3 DMC Overview

The DMC is the DSP megamodule component that reads or writes data from/to local memories, as requested by the DSP.

The DMC supports the following features:

- Two 64-bit memory accesses per cycle (sustainable)
- A memory access pair can be any combination of read and write, with no incurred penalty.
- 80KB 0-wait state LSB-banked SRAM
- L1 data cache controller (capabilities listed in [Table 14-90](#)) - 32KB maximum
- Software-programmable allocation of SRAM to cache or memory-mapped SRAM
- DMA transfer from/to SRAM
- Fair priority-based arbitration between DSP, DMA, and cache controller for access to the SRAM

- Hardware coherence maintenance with L2 (snooping)
- Block and global program-initiated cache coherence support (write-back, invalidate, and write-back-invalidate)
- Freeze and bypass mode support
- Per-page memory-protection attribute check support

The DMC operates to up to 365 MHz in the context of the IVA2.2. The DMC always operates at the same frequency as the DSP.

**CAUTION**

Clock configurations depend on core voltage, and maximum clock frequencies might not apply to production.

#### 14.3.1.4 UMC Overview

The UMC is the DSP megamodule component that reads or writes program and data from/to memory, as requested by the DMC and/or the PMC.

The UMC supports the following features:

- 64KB low-latency state SRAM (first port)
- 32KB low-latency state memory-mapped only SRAM (second port)
- 16KB low-latency ROM (second port)
- L2 unified cache controller (capabilities listed in [Table 14-91](#)) - 64KB maximum
- Software-programmable allocation of SRAM to cache or memory-mapped SRAM
- DMA transfer from/to SRAM and from ROM
- Fair priority-based arbitration between DSP, DMA, and cache controller for access to the SRAM
- Block and global program-initiated cache coherence support (write-back, invalidate, and write-back-invalidate)
- Freeze and bypass modes support
- Per-page memory protection attribute check support
- Emulation support
- Long-distance access support (noncacheable data accesses)
- Page-based memory automatic power-down (to clock-off state) and wake-up support

The UMC contains the interfaces to L2 memory, the L1D, the L1P, and the EMC. The EMC houses the interfaces to the EDMA and internal data memory access (IDMA) engines, and thus allows the UMC and ultimately the CPU to communicate with peripherals and external memory.

The UMC has two L2 memory ports, each of which is 256 bits wide. Although accesses to the two ports are initiated serially for each requestor, only one new access is initiated per UMC clock cycle, to avoid memory-bank conflicts between the ports.

The UMC has three requestor ports: the PMC, the DMC, and the EMC. Peripheral configuration and DMA/IDMA interfacing are handled by the EMC. The PMC interface to the UMC consists of a 256-bit read-only path (L1P fetch only). The DMC and the EMC interface to the UMC, and each has separate 256-bit read and write paths of its own.

The UMC operates to up to 182.5 MHz in the context of the IVA2.2. The UMC always operates at half the frequency of the DSP.

**CAUTION**

Clock configurations depend on core voltage, and maximum clock frequencies might not apply to production.

### 14.3.1.5 EMC Overview

The EMC is the megamodule component that reads or writes program and data external memory and configuration registers, as requested by the UMC.

The EMC supports the following features:

- IDMA
- 64-bit slave port for accesses from an external DMA engine and/or host to L1 or L2 memory
- 64-bit master port to serve accesses from the UMC to external memory or configuration registers

The EMC operates to up to 182.5 MHz in the context the of the IVA2.2. The EMC can operate at half or one third the frequency of the DSP.

#### **CAUTION**

Clock configurations depend on core voltage, and maximum clock frequencies might not apply to production.

### 14.3.1.6 Memory Protection Overview

The DSP megamodule memory protection architecture divides the memory map into pages. Each page has an associated set of permissions.

Memory protection provides many benefits to a system:

- Protects operating system data structures from poorly behaving code
- Helps in debugging by providing information about illegal memory accesses
- Prevents unauthorized access to sensitive data
- Allows the OS to enforce clearly defined boundaries between supervisor and user mode accesses, leading to greater system robustness

Memory protection is implemented for the PMC, DMC, UMC, and EMC, and also for the IDMA and EDMA modules.

### 14.3.1.7 INTC

The DSP megamodule INTC detects, potentially combines, and routes up to 128 system events (internal and external) to the DSP CPU interrupt lines. [Table 14-5](#) lists the global interrupt mappings of the IVA2.2 subsystem (internal and external interrupts).

The DSP CPU has 12 maskable interrupts and one exception input. The INTC includes an interrupt selector, an exception combiner, and an event combiner. The interrupt selector allows the routing of any of the 128 system events (or a combination of them) to the 12 maskable interrupts of the DSP CPU, and software determines the priorities of those system events. To handle potential conflicts, the 12 CPU interrupts have fixed priorities. The exception combiner allows the combination of any of the 128 system events to the single exception input of the DSP CPU (see [Figure 14-9](#)).

Figure 14-9. DSP Megamodule INTC Block Diagram

iva22-009

**NOTE:** Not all of the 128 event inputs of the INTC are connected to an internal or external event line. [Table 14-3](#) lists the global interrupt mapping of the DSP INTC. Some interrupts at the IVA2.2 boundary are reserved for future use or are not used by the IVA2.2 subsystem. For information about the DSP core INTC, see the C64x+ DSP documents listed in [Section 14.3.1.8, Other DSP Reference Documents](#).

#### 14.3.1.7.1 Event Type

The interrupt controller provides three types of interrupt sources to the DSP CPU:

- Single event
  - A single system event can be directly routed to a CPU interrupt input.
  - A dropped system event is supported through the CPU dropped interrupt reporting mechanism; that is, if the CPU misses the interrupt input, the system event is missed.
- Combined event
  - Up to four event combiners
  - Each combiner allows up to 32 system events to be logically ORed into a single event that can be routed to the DSP CPU.
- Exception event: This event is considered a single event, but it is directly connected to the exception input of the DSP CPU.

#### 14.3.1.7.2 Event Behavior

- Single event source: The interrupt selector routes 1 of 124 events to a DSP CPU interrupt, as

programmed in the interrupt selector registers (IC.INTMUX<sub>j</sub> registers (where j is 1 to 3). Logic in the CPU and the INTC combine to detect instances where an interrupt request is asserted before an earlier interrupt request was serviced. The INTC records the interrupt number of the first interrupt and keeps this information until directed to release the interrupt, either through reset or by application software. This record can be used as an additional system event to notify the application of an interrupt failure. Interrupts that qualify for dropped detection are defined through an IDROP mask that sets the IC.INTDMASK register. The masked IDROP event output (EVT96; see Table 14-3 ) is available as a system event that can be selected as either a DSP CPU interrupt or an exception event.

- Combined source: The event combiners create a combined event from the logical OR of 32 system-event flags qualified by a mask provided through programmable registers (IC.EVTMASK<sub>i</sub> where i = 0 to 3). The combination of the event flags creates an event that is asserted when any of the event flags included in its generation is active. Software must clear the event flags (IC.EVTCLR<sub>i</sub> where i = 0 to 3) to deassert a combined event.

---

**NOTE:** The use of event flags makes it impossible for the CPU to detect the dropping of independent system events; therefore, dropped interrupt capability is not directly supported for combined events.

---

The interrupt event combiners create four shared interrupt sources:

- EVT0: Logical OR of EVTFLAG<sub>i</sub>[31:04] (i = 0) masked by EVTMASK<sub>i</sub>[31:04] (i = 0)
- EVT1: Logical OR of EVTFLAG<sub>i</sub>[63:32] (i = 1) masked by EVTMASK<sub>i</sub>[63:32] (i = 1)
- EVT2: Logical OR of EVTFLAG<sub>i</sub>[95:64] (i = 2) masked by EVTMASK<sub>i</sub>[95:64] (i = 2)
- EVT3: Logical OR of EVTFLAG<sub>i</sub>[127:96] (i = 3) masked by EVTMASK<sub>i</sub>[127:96] (i = 3)

EVTFLAG<sub>i</sub> are the event flag registers and EVTMASK<sub>i</sub> are the event mask registers. These combined events are presented to the interrupt selection logic.

- Exception event source: As with the event combiner, the exception combiner allows multiple system events to be grouped as a single event input to the CPU, and the combiner provides mask registers to remove undesirable events. Because only one exception is input to the CPU, all mask registers work together to combine up to 128 events as a single EXCEP output. This lets the CPU service all available system exceptions.

The shared exception source is created as follows:

EXCEP: Logical OR of EF[127:04] masked by XM[127:04]

Where EF[i \* 32 + j] = EVTFLAG<sub>i</sub>[j] and XM[i \* 32 + j] = EXPMASK<sub>i</sub>[j] (i = 0, 1, 2, 3 and j = 0 to 31).

The logic is similar to that of the event combiners, except that only one combined event is routed to EXCEP.

### 14.3.1.7.3 Event Detection

The INTC contains a set of status and control registers to manage the status of system events received by the controller. These include set, flag, and clear registers covering all 128 system events. Enabling of the events is managed in the CPU for direct mapped interrupts, in the event combiner for combined events, and in the exception combiner for system exceptions. Events to the interrupt controller can be enabled/disabled only at the event source.

The event flag registers (IC.EVTFLAG<sub>i</sub> where i = 0 to 3) capture every system event received, regardless of its destination: event combiner, exception combiner, or interrupt selector. Events that are not masked by either the event combiner or the exception combiner are captured in the IC.EVTFLAG<sub>i</sub> (where i = 0 to 3) register corresponding to the event, and are used to determine when the combined event is generated. Events that are masked by either the event combiner or the exception combiner are captured in the IC.EVTFLAG<sub>i</sub> register, but do not affect when the DSP CPU interrupt is generated.

The event flags in the IC.EVTFLAG<sub>i</sub> registers retain the value of 1 for any event received. These registers are read-only and must be cleared through the write-only IC.EVTCLR<sub>i</sub> registers. The IC.EVTSET<sub>i</sub> registers can be used to manually set bits in the IC.EVTFLAG<sub>i</sub> registers, including those that are masked.

**NOTE:** Because external events are maintained by the peripheral until they are explicitly cleared by software, drop event detection does not work for external events (interrupts from peripherals external to the IVA2.2 subsystem).

**14.3.1.7.4 Event Selection**

The DSP CPU has 12 available maskable interrupts. The interrupt selector allows any of the 128 system events, either from the event inputs or from the event combiners, to be routed to any of the 12 CPU interrupt inputs (see Figure 14-10).

**Figure 14-10. Interrupt Selector Block Diagram**

iva22-010

The user can choose which of the 128 input events is mapped to each of the 12 CPU interrupts by writing the event number in the bit field corresponding to the CPU interrupt in the **INTMUXj** register. CPU priority is fixed. This event -> interrupt mapping allows software to define the priority of the event. For more information, see Section 14.4, *IVA2.2 Subsystem Basic Programming Model*.

**14.3.1.7.5 Event Combination**

The event combiner allows multiple system events to be combined as single event for routing to the interrupt selector. This allows the CPU to service all available system events, even though only 12 are available.

A set of event mask registers (IC.**EVTMASKi** where  $i = 0$  to 3), is used to program the event combiner. These registers allow up to 32 events to be combined as a single event output that is used as a single DSP CPU interrupt. The event mask bits in the **EVTMASKi** registers act as enablers for the received system events combined on the event outputs. There are four event outputs to the interrupt selector (EVT[3:0]).

By default, every system event is unmasked and combined with its associated EVT<sub>x</sub>. To mask out an event source (for example, to disable an event from being combined), the corresponding mask bit (the IC.**EVTMASKi**[y] EMy bit for EVT<sub>y</sub>) must be set to 1.

**NOTE:** Because the event masks for events 0 through 3 are combined events and thus cannot contribute to the generation of a combined event, they are reserved.

For more information, see [Section 14.4.7, Interrupt Management](#).

#### 14.3.1.7.6 Interrupt Event Error

The INTC can generate a system event internally routed to system event input EVT96. This event is generated when a DSP CPU interrupt is received while the interrupt flag (IFR, internal DSP register) is already set in the CPU. This signals possible problems in the code, such as whether interrupts were disabled for an extended time, or whether pipelined (noninterruptible) code sections were too long.

---

**NOTE:** The same strategy of register settings (events, event set, event clear, event mask) is used in the WUGEN (which is not really an INTC), which enables defining wake-up events so that they can wake up the IVA2.2 subsystem. For more information, see [Section 14.3.10, Wake-Up Generator](#).

---

For more information, see [Section 14.4.7, Interrupt Management](#). See [Section 14.4, IVA2.2 Subsystem Basic Programming Model](#), for information on associated programming.

#### 14.3.1.7.7 PDC Overview

The DSP megamodule PDC allows power management under software control. Different power-down states are defined and can be reached during a period of DSP inactivity. The PDC ensures handshakes with DSP modules so that they go to power-down state in the correct order, on request from the user, and publishes the relevant standby status to the IVA2.2 SYSC module.

The power-down attributes of the DSP components are mapped through the PDC, through the `SYS.PDCCMD` register.

For information about power-down settings, see [Section 14.4.9.3, Power-Down and Wake-Up Management](#).

#### 14.3.1.8 Other DSP Reference Documents

For more information about the DSP megamodule architecture, the instruction set, and the DSP core interrupt controller, and for a complete description of the DSP memory-mapped registers, see the following documents ([www.ti.com](http://www.ti.com)):

- *TMS320C6000 DSP Peripherals Overview Reference Guide* (TI literature number SPRU190) describes the peripherals available on the TMS320C6000 DSPs.
- *TMS320C64x Technical Overview* (TI literature number SPRU395) introduces the TMS320C64x DSP and discusses the application areas enhanced by the TMS320C64x VelociT.
- *TMS320C64x+ DSP Megamodule Reference Guide* (TI literature number SPRU871) describes the C64x+ megamodule peripherals.
- *TMS320C64x/C64x+ DSP CPU and Instruction Set Reference Guide* (TI literature number SPRU732)
- *TMS320C6000 Programmers Guide* (TI literature number SPRU198) describes ways to optimize C and assembly code for the TMS320C6000 DSPs, and includes application program examples.
- *TMS320C64x to TMS320C64x+ CPU Migration Guide* application note (TI literature number SPRAA84A)

## 14.3.2 DMA Engines

### 14.3.2.1 EDMA

The IVA2.2 subsystem has an EDMA to transfer instructions and data from/to any external memory connected to the L3 interconnect to/from the DSP megamodule L1D and L2 and, potentially, L1P (if not configured as full cache) local memories. The EDMA can also perform transfers from external memory to external memory and from DSP megamodule internal memory to DSP megamodule internal memory, with some performance loss caused by resource sharing between the read and write ports. For DSP megamodule internal memory to internal memory, use the IDMA.

For the IDMA functional description and a description of IDMA relative programming, see [Section 14.3.2.3, IDMA](#), and [Section 14.4.4.2, Internal Memory-to-Memory Transfer \(IDMA\)](#), respectively.

The EDMA is based on two primary components:

- Third-party DMA channel controller (TPCC)
- Third-party DMA transfer controller (TPTC)

There are two instances of the TPTC in the IVA2.2 subsystem.

[Figure 14-11](#) shows how the EDMA is integrated in the IVA2.2 subsystem:

- Code running on the DSP can configure the EDMA; through the DSP megamodule configuration port and the local interconnect, the code can program DMA transfers and software-trigger them by writing to the TPCC configuration registers.
- Preprogrammed DMA transfers can be triggered by external events, referred to in this chapter as DMA requests.
- The TPCC schedules DMA transfers to the TPTC DMA engines (TPTC0 and TPTC1) through dedicated local interconnect 32-bit configuration ports.
- Each TPTC issues concurrent traffic on the local interconnect through dedicated read and write 64-bit ports.
- Interrupts generated by the EDMA are routed to the DSP INTC.
- Power-management handshakes are exchanged between EDMA components and the SYSC module.

Each PaRAM entry can be used as a DMA entry (up to 64), QDMA entry (up to 8), or link entry (remaining):

- Up to 64 DMA logical channels:
  - 64 channels can be triggered explicitly by the DSP CPU (DMA entry).
  - 64 channels can be triggered by 20 external events (see [Table 14-2](#)).
  - All channels can be triggered by completion of a previous transfer in a user-programmed chain of transfers (linked entry).
  - 8 channels can be triggered automatically and indirectly by the CPU using the IDMA, reducing CPU offload for DMA configuration (QDMA entry).
- 12 interrupt lines connected to the DSP CPU
- Boundaries for synchronization with the CPU are programmable.
- Two queues holding events waiting for submission to TPTC
- Memory protection
- Each transfer can be programmed to a priority level (three possible levels).

Figure 14-12 is a block diagram of the TPCC.

Figure 14-12. TPCC Block Diagram

iva22-012

**NOTE:**

1. Although it is depicted twice in [Figure 14-12](#), there is only one physical register set for the QDMA to PaRAM set mapping block.
2. For more information, see [Table 14-3](#).

A channel is a specific event that can cause a transfer to be submitted to the TPTCs as a transfer request. The TPCC supports up to 64 DMA channels and up to 8 QDMA channels. These channels are identical, except for the ways they are triggered:

- DMA channels can be triggered by external events (such as McBSP TX Evt and McBSP RX Evt) by the software writing 1 to a given bit location or channel, by the event set register, or through chaining.
- QDMA channels are triggered automatically (auto-triggered) by the CPU using the IDMA. QDMAs allow a minimum number of linear writes (optimized for the DSP IDMA feature) to be issued to the TPCC to force a series of transfers to occur.

The TPCC arbitrates among all pending DMA/QDMA events with a fixed 64:1 and 4:1 priority encoder for DMA and QDMA events, respectively (a low channel number corresponds to a high priority). DMA events are always higher priority than QDMA events. The higher-priority event is placed in the event queue to await submission to the transfer controller, which occurs at the earliest opportunity. Each event queue is serviced in FIFO order, with a maximum of 16 queued events per event queue. If more than one TPTC is ready to be programmed with a transmission request (TR), the event queues are serviced with fixed priority, Q0 higher than Q1. When an event is ready to be queued and both the event queue and the TC channel are empty, the event bypasses the event queue and goes directly to the PaPARAM processing logic for submission to the appropriate TC. If the TR bus/PaPARAM processing is busy, the bypass path is not used. The bypass is not used to dequeue for a higher-priority event.

Events are extracted from the event queue when the TPTC is available for a new TR to be programmed into the TPTC (signaled with the empty signal, indicating an empty program register set). As an event is extracted from the event queue, the associated PaPARAM entry is processed and submitted to the TPTC as a TR. The TPCC updates the appropriate counts and addresses in the PaPARAM entry in anticipation of the next trigger event for that PaPARAM entry. The PaPARAM entry consists of eight words of DMA context, including source address, destination address, count, indexes, etc.

#### 14.3.2.1.1.2 DMA Versus QDMA

The only difference between a QDMA and a DMA transfer is the specific means of generating/recognizing TR synchronization. From the user point of view, DMA and QDMA transfer types can be combined to perform various types of transfers.

DMA channel TR synchronization can be generated from one of three sources:

- Event-triggered: The event register ([TPCC\\_ER](#)) channel  $n$  bit is set as the result of an external event. An external event is latched in the event register. If the corresponding event is enabled through the event enable register ([TPCC\\_EER](#)), this is recognized as a TR synchronization.
- Manually triggered: The event set register channel  $n$  bit is set manually to the event set register ([TPCC\\_ESR](#) and [TPCC\\_ESRH](#) registers) for channel  $n$  ([TPCC\\_ESR\[n\]](#)  $E_n$  bit or [TPCC\\_ESRH\[n\]](#)  $E_n$  bit). Manually set events do not need to be enabled to be recognized as a TR synchronization.
- Chain-triggered: The chain event register channel  $n$  ([TPCC\\_CER](#) and [TPCC\\_CERH](#) registers) bit is set when a chaining completion code is detected on the completion interface for channel  $n$ . Chain events do not need to be enabled. If a chain trigger is detected, this is always recognized as a TR synchronization.

QDMA TR synchronization occurs one of two ways:

- Auto-triggered: The QDMA event register channel  $n$  ([TPCC\\_QER](#) and [TPCC\\_QERH\[n\]](#)  $E_n$ ) bit is set when a CPU write address matches the address defined by the QDMA mapping register for channel  $n$  ([TPCC\\_QCHMAPj](#)) and the QDMA channel is enabled ([TPCC\\_QEER\[n\]](#)  $E_n$  bit field).
- Link-triggered: The [TPCC\\_QER\[n\]](#)  $E_n$  bit is set when a link update is performed on a PaPARAM address that matches the [TPCC\\_QCHMAPj](#) setting, and the [TPCC\\_QEER\[n\]](#)  $E_n$  bit is set.

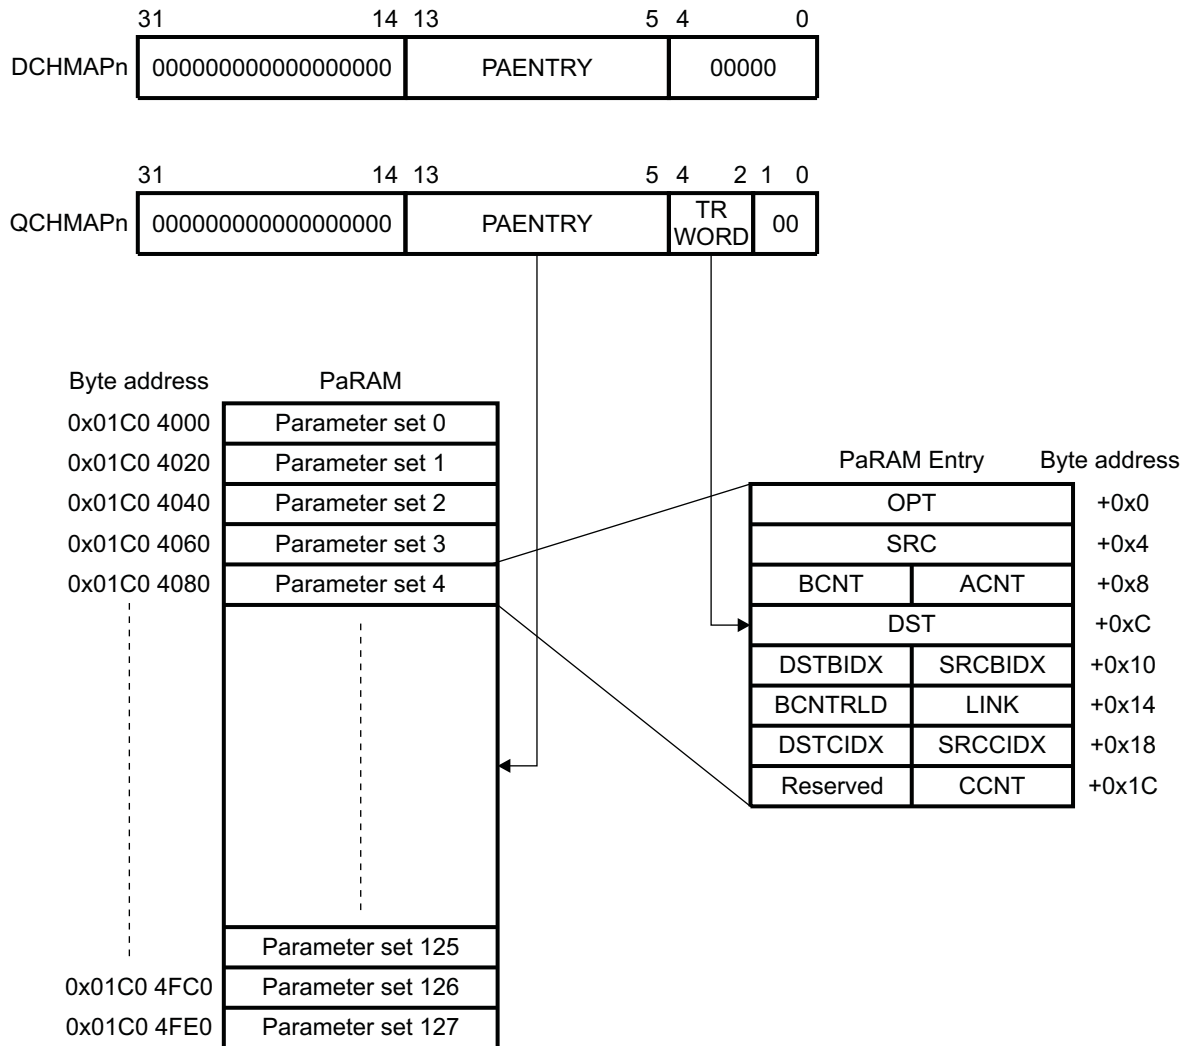

There is a subtle difference between each trigger type and the associated enablers. Event assertion always results in the [TPCC\\_ER\[n\]](#)  $E_n$  bit being set, regardless of the state of the enable ([TPCC\\_EER.E\\_n](#)). It is recognized as a TR synchronization only if enabled. Chain triggering always sets the [TPCC\\_CER\[n\]](#)  $E_n$  bit and is always treated as a TR synchronization. Manual triggering always sets the [TPCC\\_ESR\[n\]](#)  $E_n$  bit and is always treated as a TR synchronization. Auto-triggering (QDMA) sets only the event register [TPCC\\_QER\[n\]](#)  $E_n$  bit only if the corresponding event is enabled ([TPCC\\_QEER\[n\]](#)  $E_n$ ); when the [TPCC\\_QER\[n\]](#)  $E_n$  bit is set, it is always treated as a TR synchronization.

For more information, see [Section 14.4, IVA2.2 Subsystem Basic Programming Model](#).

14.3.2.1.1.3 DMA/QDMA Channel Mapping and PaRAM Entry

The DMA and QDMA channel mapping registers (TPCC\_DCHMAP<sub>i</sub> and TPCC\_QCHMAP<sub>j</sub>) allow each DMA and QDMA channel to be mapped to arbitrary locations in the PaRAM memory map. The entry is designated with a 9-bit PAENTRY (TPCC\_DCHMAP<sub>i</sub>[13:5] PAENTRY and TPCC\_QCHMAP<sub>j</sub>[13:5] PAENTRY bit fields) PaRAM entry number that defines the entry number in a 128-entry maximum PaRAM (see Figure 14-13). TPCC\_QCHMAP<sub>j</sub>[4:2] TRWORD points to the trigger word of the PaRAM entry defined by PAENTRY. A write to the trigger word results in a QDMA event being recognized.

Figure 14-13. DMA/QDMA Channel Mapping and PaRAM Entry

iva22-013

**NOTE:** Each parameter entry of PaRAM is organized as eight 32-bit words or 32 bytes, as shown in Figure 14-13.

The location of fields in each entry, as well as bit positions in the options field, must match the TR packet format as closely as possible to the requirements of the TPTC0 and TPTC1 programming. Each PaRAM entry consists of 16-bit and 32-bit parameters that correspond to the transfer geometry. For more information about the parameters, see Section 14.3.2.1.1.2, DMA Versus QDMA.

#### 14.3.2.1.1.4 Types of TPCC Transfers

The TPCC streamlines transfers into an orthogonal transfer structure that is always defined by three dimensions. Of the three dimensions, only two synchronization types are supported: 1D synchronized transfers and 2D synchronized transfers; 3D synchronized transfers can be logically achieved by chaining.

The following terms are used:

- 1-dimension (1D) transfer or array: ACNT contiguous bytes transfer. For information about the 1D transfer programming model, see [Section 14.3.2.1.1.5, Transfer Synchronization](#).
- 2-dimension (2D) transfer or frame: BCNT arrays of ACNT bytes transfer. Each array transfer in 2D transfer is separated from the other transfers by an index programmed through the TPCC.SBIDX or TPCC.DBIDX registers.
- 3-dimension (3D) or block: CCNT frames of BCNT arrays of ACNT bytes. Each transfer in the third dimension is separated from the previous transfer by an index programmed by the TPCC.SCIDX or TPCC.DCIDX registers. The reference point for the index depends on the synchronization type.

#### 14.3.2.1.1.5 Transfer Synchronization

In a 1D synchronized transfer, each TPCC TR synchronization triggers the transfer of the first dimension of ACNT bytes, or one array of ACNT bytes. In other words, each TR packet consists of transfer information for only one array. Arrays can be separated by SBIDX and DBIDX, as shown in [Figure 14-13](#), where the start address of array N equals the start address of array 1 plus SRC or DST BIDX. Frames can be separated by SCIDX and DCIDX. For 1D synchronized transfers, after the frame is exhausted, the address is updated by adding (S|D)CIDX to the beginning address of the last array in the frame.

Contrast this to the (S|D)CIDX update in 2D synchronized transfers, which are referenced from the beginning address of the first array in the previous frame. For information about parameter updates, see [Section 14.3.14, Error Reporting](#).

In a 2D synchronized transfer, each TR synchronization triggers the transfer of two dimensions or one frame. In other words, each TR packet conveys information for one entire frame of BCNT arrays of ACNT bytes. Arrays can be separated by SBIDX and DBIDX, as shown in [Figure 14-15](#). Frames can be separated by SCIDX and DCIDX. For 2D synchronized transfers, after a TR for the frame is submitted, the address is updated by adding (S|D)CIDX to the beginning address of the beginning array in the frame. Contrast this to the (S|D)BIDX update in 1D synchronized transfers. For information about parameter updates, see [Section 14.3.14, Error Reporting](#).

#### 14.3.2.1.1.6 DMA Channel Prioritization

If multiple trigger sources (event trigger/chain trigger/manual trigger) for a single channel are active at the same time, the TPCC services events in the following order:

1. Event trigger (through event register [ER])
2. Chain trigger (through chain event register [CER])
3. Manual trigger (through event set register [ESR])

#### 14.3.2.1.1.7 Transfer Completion

Transfer completion can be used for two different mechanisms in the TPCC:

- Generating chained events
- Generating interrupts to an external processor

The underlying mechanism for both features is the same. The user programs the PaPARAM Options field with a specific transfer completion code (TPCC\_OPTm[17:12] TCC) and indicates whether that completion code is to be used to generate a chained event and/or to generate an interrupt on completion of a transfer (either or both can be done). The user can selectively program whether completion signaling is enabled for the final TR of a PaPARAM set, for all except the final TR of a PaPARAM set, or for all TRs of a PaPARAM set. The specific TCC value (6-bit binary value) programmed by the user dictates which bit of the 64-bit CER and/or interrupt pending register (IPR) is used.

There is no direct correlation between the TCC value used for a specific PaRAM entry and the channel number for that entry. Software controls the allocation of TCC values. There is always a 1:1 relationship between the TCC value and the IPR bit and/or the CER bit set when that transfer completes. For example, completion of the PaRAM entry for channel 0 can chain-trigger the PaRAM entry for channel 1.

#### 14.3.2.1.2 Third-Party Transfer Controller

The TPTC is the DMA transfer engine that generates transfers as programmed in dedicated working registers, using two dedicated master ports: a read-only port and a write-only port.

---

**NOTE:** The port data bus width of the instances of the TPTC is fixed at 64 bits.

---

##### 14.3.2.1.2.1 TPTC Features

The TPTC features are as follows:

- Pipelined transfers (multiple inflight transfers)
- Background programming
- 2D or 1D transfer
- Increment addressing modes
- Clock-stop handshaking with the SYSC controller
- Programmable tracking of transfer completion
- 2D qualifications of transfers to allow 2D bandwidth optimization

Two instances of the TPTC generate concurrent traffic on the IVA2.2 local interconnect. Each TC controller consists of the following components:

- DMA program register set: Stores the context for the DMA transfer that is loaded into the active register set on completion of the current active register set. The CPU or TPCC programs the program register set, not the active register set. For typical stand-alone operation, the CPU programs the program register while the TC services the active register set. The program register set includes ownership control that synchronizes the CPU software and the DMA.
- Source DMA active register set: Stores the context (src/dst/cnt/etc) for the DMA transfer request in progress in the read controller. The active register set is split into independent source and distant register halves, because the source local interconnect controller and distant local interconnect controller operate independently of each other.
- Distant DMA register set: Stores the context (src/dst/cnt/etc) for the DMA transfer request in progress, or pending, in the write controller. The pending register sets are required to allow the source controller to begin processing a new TR while the distant register set is still processing the previous TR.
- Channel FIFO: Temporary holding buffer for inflight data. The read return data of the source peripheral is stored in the data FIFO and then written to the destination peripheral by the write command/data bus.
- Read controller/local interconnect read interface: The local interconnect read interface issues optimally sized read commands to the source peripheral, based on a burst size of 64 bytes and the available landing space in the channel FIFO.
- Write controller/local interconnect write interface: The local interconnect write interface issues optimally sized write commands to the destination peripheral, based on a burst size of 64 bytes and available data in the channel FIFO.
- Completion interface: The completion interface sends completion information to the TPCC for posting interrupts in the TPCC.
- Configuration port: Slave interface that provides read/write access to program registers, and provides read access to all memory-mapped TC registers. For information about TPTC registers, see [Section 14.5, IVA2.2 Subsystem Register Manual](#).

[Table 14-4](#) lists the hardware settings.

[Figure 14-14](#) shows the internal structure of the TPTC and its connection to the TPCC.

**Figure 14-14. TPTC Block Diagram**

The primary responsibility of the TPTC is to perform read and write transfers through the local interconnect to the slave peripherals, as programmed in the active and program register sets:

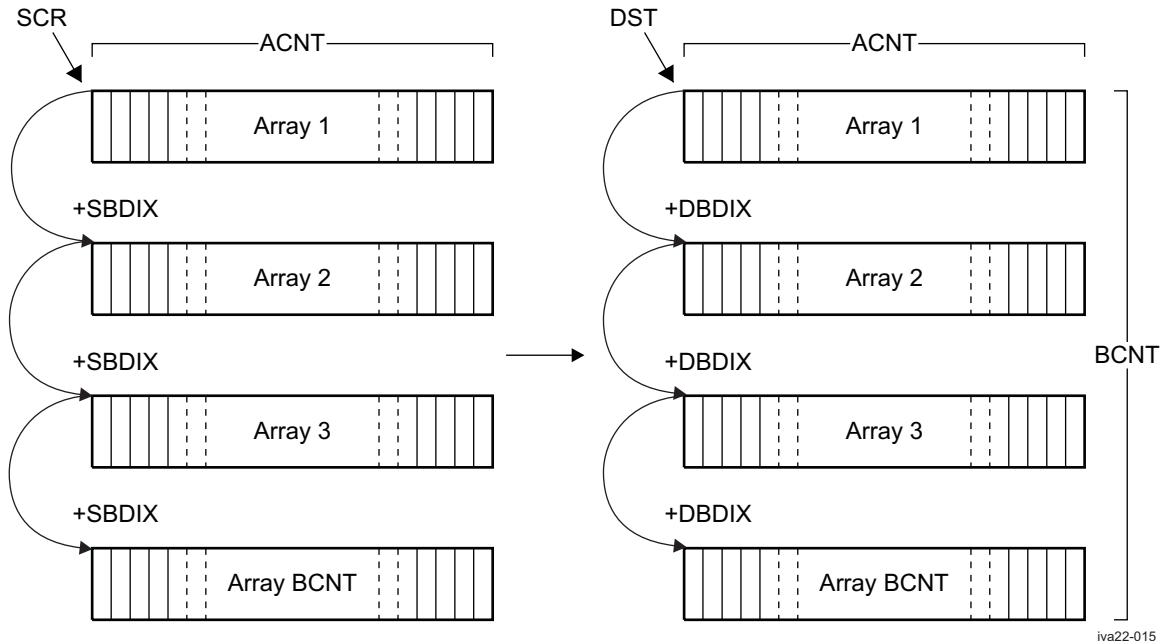

- In the TC stand-alone use model, the user directly programs the program and active register sets for a given channel (TPTC0 or TPTC1). Because of the TPCC, this mode is not the use case targeted for device applications, so it is not emphasized in this chapter. For information about its programming model, see [Section 14.4.4.6.6, Direct Configuration to Transfer Channel \(Not Recommended\)](#).
- In the TC external-control use model, the user does not directly program the active and program register sets. Instead, the TPCC is the user interface to the EDMA system, and the TPTCs (TPTC0 and TPTC1) are slaves to the TPCC. This is the use case of the EDMA in device applications.

#### 14.3.2.1.2.2 Transfer Geometry

The TPTC supports a transfer geometry fully defined by the registers summarized here (see [Figure 14-15](#)).

- OPTx = options, (where x = 0, 1)
  - SAM = Source address mode, controls whether the source array is from incrementing addresses or from a single FIFO address
  - DAM = Distant address mode, controls whether the destination array is to an incrementing address or to a single FIFO address
  - FWID = Controls the width of the FIFO
- SRC = Source address
- DST = Distant address
- CNT = BCNT, ACNT
  - ACNT = Number of bytes in each array
  - BCNT = Number of arrays in each TR
- BIDX = DBIDX, SBIDX
  - SBIDX = Source B-dimension index, defines the address offset between starting addresses of each source array
  - DBIDX = Distant B-dimension index, defines the address offset between starting addresses of each destination array

Figure 14-15. Transfer Geometry

iva22-015

**NOTE:** Many Texas Instruments DMA controllers employ a concept of element size and element indexing. To maintain orthogonality, the concept of element size has been dropped. An element-indexed transfer is logically achieved by programming ACNT to the size of the element and BCNT to the number of elements that must be transferred.

#### 14.3.2.1.2.3 Tracking Transfers

Each TPTC channel consists of three register sets: a program register set, a source-active register set, and a distant FIFO register set. The status of each of these register sets is indicated by the PROGBUSY, SRCACTV, DSTACTV, and WSACTV status bits, which are user-readable in the TPTCj\_TCSTAT register.

The program register set (TPTCj\_POPT, TPTCj\_PSRC, TPTCj\_PCNT, TPTCj\_PDST, TPTCj\_PBIDX, and TPTCj\_PMPPRXY) is never modified by the TPTC, because they are simply holding registers processed by the active register sets. The source active register set (TPTCj\_SAOPT, TPTCj\_SASRC, TPTCj\_SACNT, TPTCj\_SADST, TPTCj\_SABIDX, TPTCj\_SAMPPrXY, TPTCj\_SACNTRL, TPTCj\_SASRCBREF, and TPTCj\_SADSTBREF) tracks commands for the source side of the transfer, and the distant FIFO register set (TPTCj\_DFOPTi, TPTCj\_DFSRCi, TPTCj\_DFCNTi, TPTCj\_DFDSTi, TPTCj\_DFBIDX<sub>i</sub>, and TPTCj\_DFMPPrXY<sub>i</sub>) tracks commands for the distant side of the transfer.

As the source and distant controllers process a TR, the SRC, DST, and CNT fields must be continuously updated as commands are issued. A reference value for these registers is also maintained. The active register set uses the reference address (SRCBREF and/or DSTBREF) to calculate the addresses of the subsequent arrays in a transfer. This is required because subsequent arrays are defined as an offset from the starting address of the current array. Similarly, when a new array begins, the CNT must be restored (from CNTRL) to the originally programmed value and decremented as the new array is processed.

The following summarizes register use for the active register sets:

- Static fields
  - OPT
  - BIDX = DBIDX/SBIDX
- Dynamic fields
  - SRC = Source address of the next read command to be issued
    - Tracked by source active register set

- DST = Distant address of the next write command to be issued
  - Tracked by distant FIFO register set
- CNT = BCNT/ACNT
  - BCNT = Number of arrays remaining to be transferred. This includes the current array; that is, BCNT is decremented after all commands for an array are issued (or at least after all read or write commands are scheduled).
  - ACNT = Number of bytes remaining to be transferred
  - Tracked independently in source and distant FIFO register sets
- Reference fields
  - CNTRLD = ACNTRLD only
    - CNTRLD.ACNTRLD is set with the initial CNT.ACNT value. The reload value is copied into CNT.ACNT when CNT.ACNT decrements to 0.
    - Tracked independently in source and distant FIFO register sets
 Because a command is complete when BCNT decrements to 0, there is no BCNT reload value.
  - SRCBREF = Source address reference points to the starting address of the array being read. The starting address of the next array is calculated as SRCBREF + SBIDX.
    - Tracked by source active register set
  - DSTBREF = Distant address reference points to the starting address of the array being written. The starting address of the next array is calculated as DSTBREF + DBIDX.
    - Tracked by distant FIFO register set

#### 14.3.2.1.2.4 Completion Interface to TPCC

The TPCC can request that the TPTC send completion information to the TPCC when a TR completes. Completion status is requested in the TR options registers ([TPTCj\\_DFOPTi\[20\]](#) TCINTEN and [TPTCj\\_DFOPTi\[22\]](#) TCCHEN bits, and [TPTCj\\_DFOPTi\[17:12\]](#) TCC where  $i = 0$  to 3 when  $j = 0$  and  $i = 0$  or 1 when  $j = 1$ ).

If TCINTEN or TCCHEN is set to 1, the TPTC must return completion information on completion of the entire TR. The TPCC uses completion information for chaining (enabled by TCCHEN) or for posting interrupts (enabled by TCINTEN).

The TPTC generates status conditions based on completion of a transfer ([TPTCj\\_INTSTAT\[1\]](#) TRDONE bit) and based on the program register set transitioning to the downstream registers ([TPTCj\\_INTSTAT\[0\]](#) PROGEMPTY bit).

These two conditions can be enabled by the corresponding bits in the [TPTCj\\_INTEN](#) register to generate an interrupt to the DSP CPU through the TCERRINTx interrupt line (TCERRINT0 for TPTC0 and TCERRINT1 for TPTC1). For the event mapping of these interrupt lines, see [Table 14-2](#).

---

**NOTE:** Status bits TRDONE and PROGEMPTY are always available and are stored in the [TPTCj\\_INTSTAT](#) register regardless of use model and regardless of whether the corresponding bits are enabled. Typically, these bits are not used in the TPCC use model. They are used in a stand-alone use model in which the user directly programs the TC.

---

For more information about EDMA completion and its programming model, see [Section 14.4.4.1, Transfers From/to Device Memories/Peripherals \(EDMA\)](#).

#### 14.3.2.1.3 EDMA Hardware Parameters

[Table 14-4](#) lists the hardware parameter settings for the IVA2.2 subsystem.

**Table 14-4. IVA2.2 EDMA Hardware Parameters**

Module		Parameter	IVA2.2
EDMA	TC	FIFO size for TC0	256 bytes
		FIFO size for TC1	128 bytes
		Data bus width	64 bits
		TR pipelining depth TC0	4
		TR pipelining depth TC1	2
		Endianness	Little
		Burst size	64
	CC	Number of DMA channels	64
		Number of QDMA channels	8
		Number of PaRAM entries	128
		Number of Event Qs	2
		Number of TPTCs	2

**NOTE:** The TR pipelining depth controls the number of read TRs for a given transfer channel that can be serviced by the source transfer controller without being serviced by the distant transfer controller. This dictates the amount of storage required in the distant queue channel registers for inflight TRs

The user cannot directly program burst size, as with the sDMA, but must rely on the ACNT/BCNT and issue 1D synchronization transfers to do so.

#### 14.3.2.2 EDMA Access to Video Accelerator/Sequencer

To improve performance and to offload themselves, the DSP megamodule and sequencer can both program the EDMA in IVA2.2 to transfer memory to/from the video accelerator/sequencer (sequencer, iLF, iME) to/from external memories. The DSP megamodule programs the EDMA through the IVA2.2 local interconnect, whereas the sequencer programs the EDMA through the video and sequencer local interconnect. The EDMA can access the following module registers and memories in the video accelerator/sequencer:

- iME configuration registers
- iLF configuration registers
- Sequencer memories
- SL2 memory (access through the IVA2.2 local interconnect)

The DMA accesses the video and sequencer modules with the memory mappings listed in [Table 14-5](#).

**Table 14-5. EDMA Memory Mapping for the Video Accelerator/Sequencer**

Device Name	Start Address (Hex)	End Address (Hex)	Size (in Kbytes)

### 14.3.2.3 IDMA

The IDMA is a simple DMA engine that performs block transfers between any two memory locations local to the DSP megamodule. A local memory has a controller that is included in the DSP megamodule. Local memory can be L1P, L1D, or L2 memories or DSP megamodule port configuration for an offloaded configuration. The IDMA controller consists of two DMA channels (channel 0 and channel 1) that can be independently programmed (a dedicated set of registers) to perform block moves between internal DSP megamodule resources.

IDMA channel 0 is used only to configure registers of IVA2.2 modules connected to the DSP megamodule configuration port, and it is useful for the DMA PaRAM entries.

To allow an easy configuration of IVA2.2 modules, the IDMA channel contains five registers: status, mask, source address, destination address, and window count.

For information about the use of channel 0 for an offloaded configuration, see [Section 14.4.4.6.5, Offloaded Configuration \(Using IDMA\)](#).

IDMA channel 1 allows transfers between any two DSP megamodule local internal memories (L2, L1P, L1D). Channel 1 is intended for background transfers in internal memory, such as block moves between the relatively high-latency L2 and the zero-latency L1D SRAM. This lets the CPU process data directly within L1D with minimal CPU impact.

For more information, see [Section 14.4.4.2, Internal Memory-to-Memory Transfer \(IDMA\)](#).

### 14.3.3 MMU

The IVA2.2 MMU communicates accesses from the DSP core of the IVA2.2 subsystem to the L3 interconnect, mapping the 4G bytes of the DSP virtual addresses to any place in the 4G-byte address space of the device.

At reset, the MMU is disabled, and the IVA2.2 DSP CPU can access device global memory mapping from the 0x1100 0000 address. The range of addresses 0x00000000 to 0x10FF FFFF is reachable only by the DSP CPU, because it performs its own internal memory-mapping function. For more information, see [Chapter 2, Memory Mapping](#).

The IVA2.2 MMU main features are:

- 32 entries/fully associative translation lookaside buffer (TLB)
- One interrupt line to the MPU
- 32-bit virtual addresses, 32-bit physical addresses
- 4-KB and 64-KB pages, 1-MB section, 16-MB supersection
- Predefined (static), software-driven (interrupt-based) or table-driven (hardware table-walker) software translation strategies

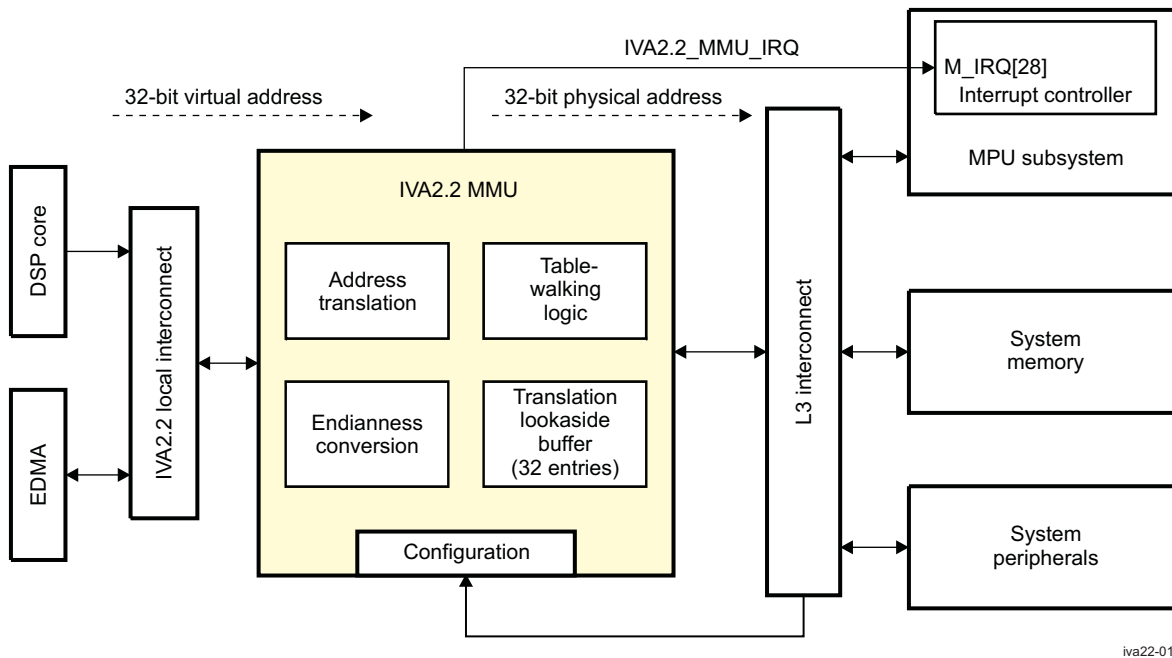

---

**NOTE:** The endianness conversion capability of the MMU module is not used in the IVA2.2 subsystem (the DSP is configured as a little-endian processor in the device). With this configuration, the MMU2.MMU\_RAM[9] ENDIANNESSESS bit setting is ignored, even if the user changes the value.

---

Figure 14-16 shows the integration and functionality of the IVA2.2 MMU module.

**Figure 14-16. IVA2.2 MMU Block Diagram**

### 14.3.3.1 MMU VA-to-PA Translation

The IVA2.2 MMU translates the 32-bit DSP external addresses to physical addresses in the 32-bit MPU address space. Address translation is performed by a translation table structure (TTB) that maps the most-significant bits (MSBs) of the DSP byte address to another set of MSBs of a 32-bit MPU byte address. The least-significant bits (LSBs) of the DSP-generated byte address are used as page/section indices in the address translations and are not altered when forming the new 32-bit physical address. The TTB translations are expedited by a TLB that serves as a cache of recently used page translations. The address mapping can be programmed at the TTB level or by writing the TLB entries directly. The IVA2.2 MMU contains 32 TLB entries that can be configured to remap 4-KB, 64-KB, 1-MB, or 16-MB segments of memory.

The TLB can be managed statically or dynamically (through the use of interrupts) by the MPU OS, but the MMU also includes hardware table-walking logic that lets the MMU autonomously traverse the page table on a TLB miss. On a TLB miss, the translation table-walking logic automatically retrieves the information from the translation table stored in physical memory and updates the TLB cache.

Figure 14-17 shows the TTB structure in detail.

**Figure 14-17. IVA2.2 MMU Translation Table Hierarchy**

iva22-017

**NOTE:** The MMU passes the lower bits of the virtual address unchanged.

### 14.3.3.2 MMU Configuration

If the IVA2.2 MMU requires software intervention, the MPU services the event; IVA2.2 MMU service requests are signaled to the MPU with a dedicated interrupt, M\_IRQ[28].

Generally, the MMU is initialized at boot time, but it can also be dynamically reprogrammed. Typically, the MMU is programmed by the MPU through the IVA2.2 slave port on the L3 interconnect when a new task is created on the IVA2.2 subsystem. But the DSP also has access to the MMU configuration registers for the save and restore process. At reset, MMU is disabled and DSP virtual addresses are passed directly through as physical addresses (not translated). IVA2.2 MMU configuration registers are at system base address 0x5D00 0000.

For more information about the functionality of the IVA2.2 subsystem MMU module, including interrupts, register descriptions, and programming model, see [Chapter 8, Memory Management Units](#).

### 14.3.4 Video Sequencer

The sequencer module, referred to as sequencer or video sequencer, is an ARM968E-S based microcontroller that handles maintenance functions for the video hardware accelerators implemented in IVA2.2.

The sequencer is connected to the video accelerator and local interconnect in an accelerator design. The sequencer provides the following functions:

- Accelerator configuration
- Interrupt handling
- Local register access
- Host communication

Figure 14-18 is a block diagram of the sequencer.

The sequencer uses the little-endian convention.

**Figure 14-18. Sequencer Block Diagram**

The sequencer include two types of memory:

- Instruction tightly coupled memory (ITCM), an 8K-byte instruction memory, used by the ARM968E-S to fetch its instruction. This memory must be filled by DMA.
  - Data tightly coupled memory (DTCM), a 4K-byte data memory, used to store data
- These two memories can be reached from the ARM968E-S and from the local interconnect.

#### 14.3.4.1 DMA Access

The sequencer can fully control the EDMA included in the IVA2.2 subsystem. The sequencer accesses the same EDMA registers as the DSP megamodule, but the base address is 0x2 0000. The sequencer can use the EDMA to initialize the ITCM, DTCM.

#### 14.3.4.2 Sequencer Interrupts

The sequencer module has an interrupt controller, IRQ, to capture external interrupts. External interrupts typically come from the EDMA, local interconnect, DSP megamodule, or one of the video hardware accelerators. For a complete list of externally generated interrupts, see Table 14-6. All interrupts are a one-clock-wide active-high pulse. An interrupt causes the appropriate bit in the IVA22.SEQ\_IRQSTATE register to be set. Before a second interrupt on the same input can occur, the interrupt must be cleared at the source. Any interrupt can be enabled (disabled) by clearing (setting) the appropriate bit in the IVA.SEQ\_IRQMASK register. If at least one enabled interrupt is captured, an FIQ interrupt is signaled to the sequencer.

The FIQ interrupt to the ARM remains active until all enabled interrupts are cleared in the IRQ when 1 is written to the appropriate bits of the IVA.[SEQ\\_IRQSTATE](#) register. The externally generated interrupts must be cleared at the source before being cleared in the IRQ.

The interrupt is captured, regardless of whether the sequencer is in IDLE state (standby). If an unmasked interrupt occurs while the sequencer is idle, the sequencer initiates its wake-up process.

**Table 14-6. Sequencer External Interrupt**

IRQ#	INT NAME	INT SOURCE	INT DESCRIPTION
0	iME interrupt	iME	iME interrupt notification
1	iLF interrupt	iLF	iLF interrupt notification
2	Reserved	N/A	N/A
3	Reserved	N/A	N/A
4	EDMA access error	Local interconnect	Video accelerator/sequencer local interconnect notification of a DMA access error
5	Sequencer access error	Local interconnect	Video accelerator/sequencer local interconnect notification of a sequencer access error
6	Reserved	N/A	N/A
7	Reserved	N/A	N/A
8	HOST interrupt	DSP megamodule	Software interrupt for DSP megamodule communication
9	DMA interrupt 0	DMA	Completion interrupt from DMA 0
10	DMA interrupt 1	DMA	Completion interrupt from DMA 1
11	DMA interrupt 2	DMA	Completion interrupt from DMA 2
12	DMA interrupt 3	DMA	Completion interrupt from DMA 3
13	DMA interrupt 4	DMA	Completion interrupt from DMA 4
14	DMA interrupt 5	DMA	Completion interrupt from DMA 5
15	DMA interrupt 6	DMA	Completion interrupt from DMA 6
16	DMA interrupt 7	DMA	Completion interrupt from DMA 7
17	DMA interrupt 8	DMA	Completion interrupt from DMA 8
18	DMA interrupt 9	DMA	Completion interrupt from DMA 9
19	DMA interrupt 10	DMA	Completion interrupt from DMA 10
20	DMA interrupt 11	DMA	Completion interrupt from DMA 11
21	DMA interrupt 12	DMA	Completion interrupt from DMA 12
22	DMA interrupt 13	DMA	Completion interrupt from DMA 13
23-31	Reserved	N/A	N/A

#### 14.3.4.3 Sequencer to DSP Megamodule Interrupts

To support a mailbox function between the sequencer and the DSP megamodule CPU, the SEQ\_MBX signal interrupts the DSP megamodule when mail is available. The sequencer can set this line high through a write of 1 to the IVA22.[SEQ\\_SWISSET](#) register. The host can clear this interrupt through a write of 1 to the IVA22.[SEQ\\_SWICLR](#) register.

The sequencer DTCM memory can be used as shared memory between DSP and sequencer.

#### 14.3.4.4 I/O Interrupts

[Table 14-7](#) lists interrupt signals at the sequencer boundary. [Table 14-99](#) summarizes the interrupt register address mappings.

**Table 14-7. Sequencer Out Interrupt Interface**

Interrupt Name	Direction	Description	Synchronous to
SEQ_MBX	Out	Software interrupt (from mailbox register)	SEQ_CLK

#### 14.3.4.5 IRQ Generic

The sequencer is connected to the FIQ interrupt. The IRQ interrupt is not used and is tied off to inactive in the sequencer.

Two registers are defined for operations on IRQs:

- The IVA.[SEQ\\_IRQSTATE](#) register keeps track of input events. Each event has its own bit in IVA.[SEQ\\_IRQSTATE](#). When the bit is set after an active pulse on the associated event line, this bit is kept active (sticky) until the user explicitly writes 1 to it.
- The IVA.[SEQ\\_IRQMASK](#) register controls the sensitivity of the interrupt line to input events. Each event has its own bit in the IVA.[SEQ\\_IRQMASK](#) register. When the user writes 1 to a bit, the associated active event is not allowed to trigger an interrupt. When the user writes 0, the associated active event triggers an interrupt.

For more information about these registers, see [Section 14.5](#) , *IVA2.2 Subsystem Register Manual*.

#### 14.3.4.6 Sequencer Core

The ARM968E-S processor is used in the core. For more information, see the *ARM968E-S ARM Technical Reference Manual*.

#### 14.3.4.7 Exception Handling

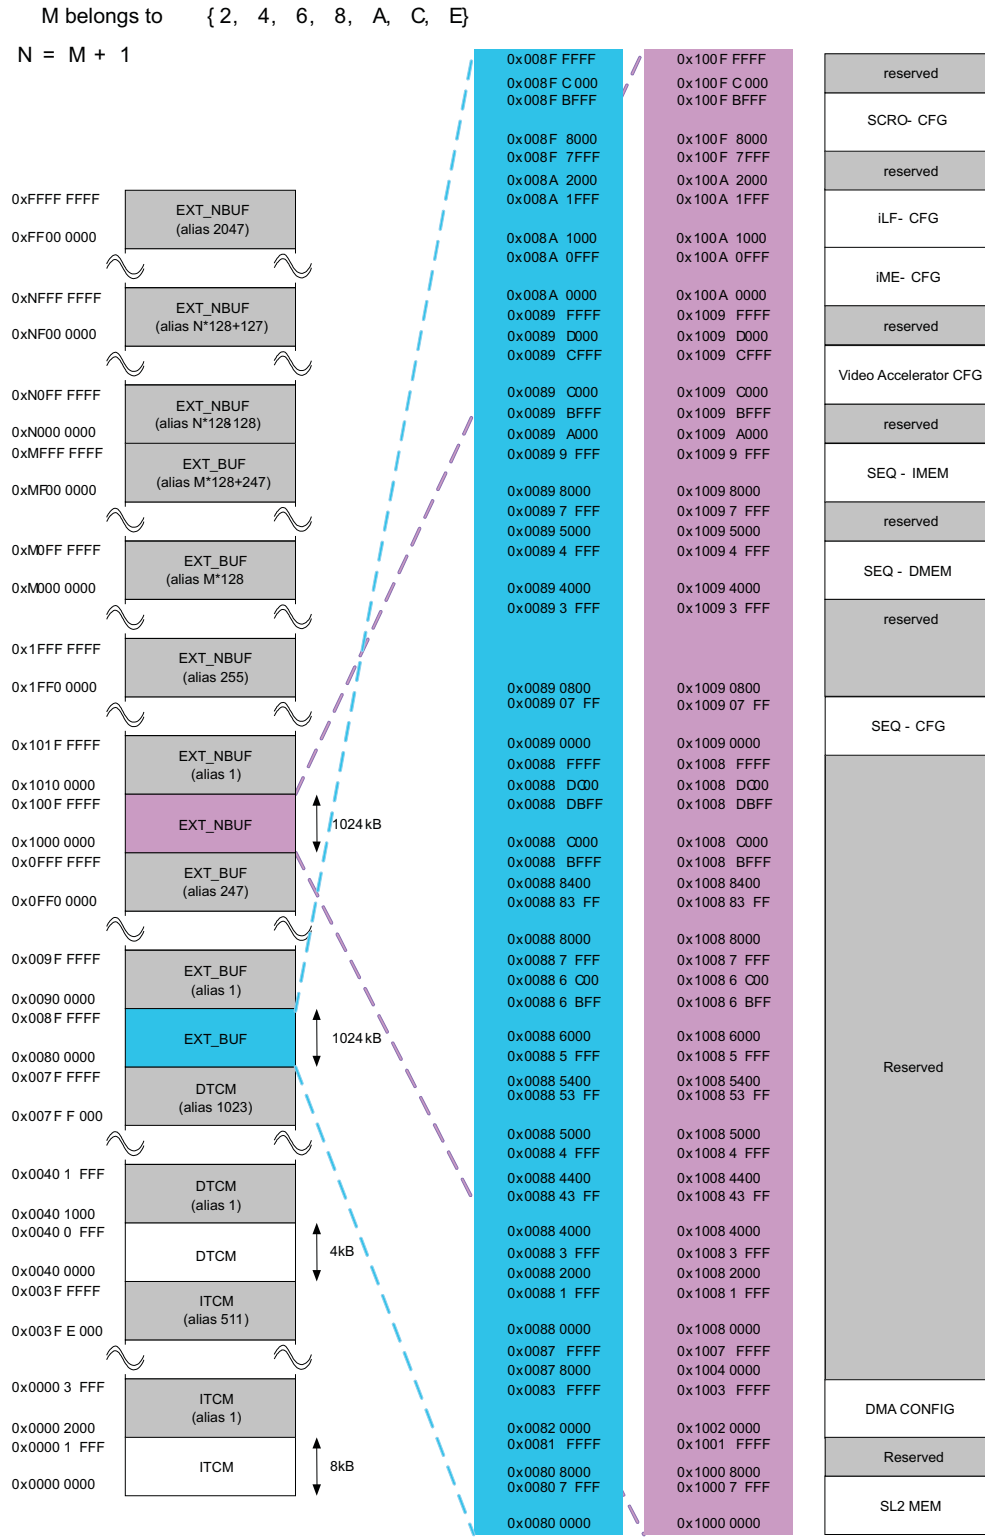

The sequencer slave port responds with an in-band error (SResp = ERR) in the following condition:

- Nonmapped address (reserved space)

#### 14.3.4.8 Sequencer Memory Mapping

[Figure 14-19](#) shows the sequencer memory mapping.

Figure 14-19. Sequencer Memory Mapping

### 14.3.5 iLF and iME Common Part

iLF and iME are video accelerator modules that share the following properties:

- Commands
- State-machine
- Instruction set (except data-operator-oriented instruction)
- Debug mode

#### 14.3.5.1 iLF/iME Control

The iLF/iME coprocessors are controlled in two ways:

- **Direct-write mode:** For simple code with few instructions. The processor (DSP megamodule or video sequencer) initializes the iLF/iME coprocessor, and then writes a small instruction sequence. For instructions to be performed, all iLF/iME registers must be initialized individually, and the processor (sequencer or DSP megamodule) must tightly control the iLF/iME coprocessor.
- **Normal mode:** For application code with many instructions. The processor configures a small set of iLF/iME registers, and then creates a memory image of the iLF/iME parameters and an instruction sequence in the last 32K bytes of the L2 flat memory. A single instruction is written in the iLF/iME command register to specify where the iLF/iME coprocessor must fetch its instruction and retrieve its parameters. Normal mode allows parallel processing and can be highly optimized by using IDMA and different cache levels.

Both modes require an instruction set and commands to control the execution of the instructions. [Section 14.3.5.1.1, Commands](#), and [Section 14.3.5.2, Instruction Set](#), describe these tools.

##### 14.3.5.1.1 Commands

Commands for controlling the iLF/iME EXECUTION states must be written in the IVA.iLF\_COMMANDREG/IVA.iME\_COMMANDREG register at address offset 0xFFC from the base address of iME/iLF. [Table 14-8](#) describes the iLF/iME execution commands.

**Table 14-8. iLF/iME Common Commands**

Command	Description	Code
RRead()	Read register value.	-
RWrite()	Write register value.	-
StartSeq()	Forces the start of execution at the first instruction of the current sequence (PC reset with a pipeline flush engaged, regardless of any memory-access stall). CPU status goes to EXECUTING state (all other flags are cleared), cycle counter is reset and starts counting IRQ. Log content is reset.	0x1
StopSeq()	Forces the stop of execution. CPU state goes to INITIALIZED. No status information is touched. DSP engine pipeline flush is triggered (regardless of any memory-access stall). The DetectedStopSeq flag is set when this command is received and cleared when INITIALIZED state is reached.	0x2

The commands listed in [Table 14-8](#) are mapped through the video and sequencer interconnect memory map, at offset 0xFFC from the base address in the iLF/iME address space associated with a write operation. Register read and write commands are direct reads and writes to the corresponding register address.

##### 14.3.5.1.2 Execution States

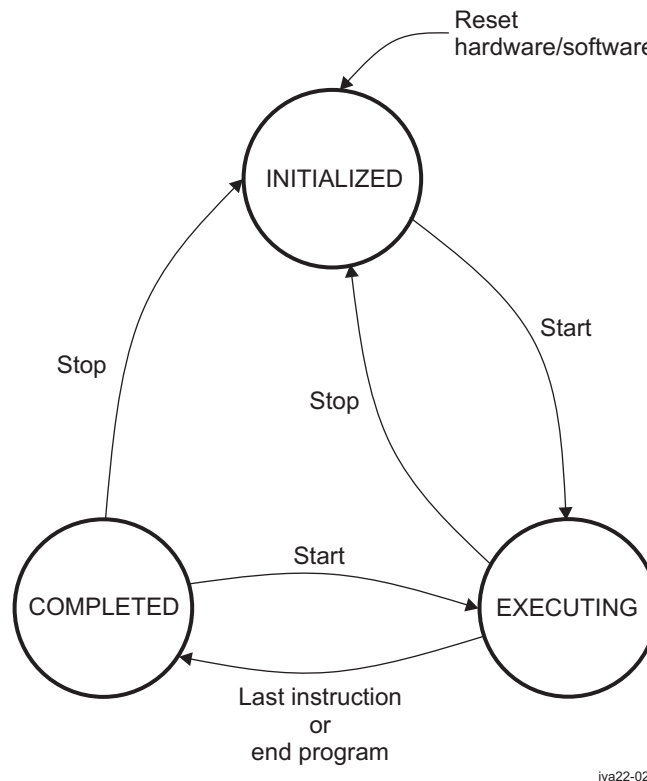

[Table 14-9](#) lists the execution states of the iLF/iME modules. The IVA.iLF\_CPUSTATUSREG[24:25] EXECSTATE/IVA.iME\_CPUSTATUSREG[24:25] EXECSTATE field shows the current execution state of the iLF/iME coprocessor.

**Table 14-9. iLF/iME Execution States**

State	Code in EXECSTATE Field	Description
INITIALIZED	0x00	State after reset and after a stop command
EXECUTING	0x10	iLF/iME is computing data; state after a start command
HALTED	0x01	In debug mode only, state reached after EXECUTING state
COMPLETED	0x11	State reached when EndPgm instruction is executed or after the last instruction

The simple state-machine in Figure 14-20 shows how the EXECUTING state works in the iLF/iME coprocessor.

**Figure 14-20. iLF/iME Execution State-Machine**

When the coprocessor is in EXECUTING state, modifications must not be made in the iLF/iME register. The register can be read, but not written. If a write is attempted during execution, an error is logged in the IVA.iLF\_CPUSTATUSREG[26]/IVA.iME\_CPUSTATUSREG[26] WRITEREGERROR bits and the write is not performed.

**NOTE:** A write can be issued on the IVA.iLF\_COMMANDREG/IVA.iME\_COMMANDREG register at address 0xFFC, even if the coprocessor is in EXECUTING state.

**14.3.5.2 Instruction Set**

The iLF/iME coprocessors provide a reduced instruction set to load, prepare, and compute data. iLF/iME instructions are multicycle instructions. Table 14-10 lists the instructions available in the iLF and iME coprocessors.

**Table 14-10. iLF/iME Common Instruction Set List**

Instruction	Parameters	Parameter Type	OPcode (hexa)
LoadPStack() iLF only	Stack index where SL2 offset is stored Parameter to specify whether SL2 offset is stored on stack or on instruction Stack offset in SL2 (in L2. Loads 128 bytes starting at 128 bits aligned location).	@field0 P0 P1P5	0x0a
LoadPStack() iME only	Stack offset in SL2 (in L2. Loads 128 bytes starting at 128 bits aligned location).	P1P5	0x0a
LoadInstBuf()	Program start offset in SL2 (16-bit, aligned on a 16-byte boundary). Number of instructions (instructions must be aligned in 64-bit bins, padded with zeroes towards the MSBs)	P1P5 P0	0x10
GenerateIT()	None (triggers interrupt from inside the program, if the interrupt is enabled)		0x1e

**Table 14-10. iLF/iME Common Instruction Set List (continued)**

Instruction	Parameters	Parameter Type	OPcode (hexa)
Endpgm()	None (indicates program execution complete)		0x1f

Each instruction is stored in a set of two 32-bit registers. There are 128 sets of two instruction registers in the iLF and 256 sets of two instruction registers in the iME. The iLF can buffer 128 instructions at a time, and the iME can buffer 256 instructions at a time.

There are two ways to write instructions in the iLF/iME registers:

- Write the instruction registers individually (for more information about register addresses, see [Section 14.5, IVA2.2 Subsystem Register Manual](#)). This method corresponds to the direct-write/tightly coupled control mode.
- Write the instructions on the last 32K bytes of the L2 flat RAM. Then write the load instruction buffer with the correct parameters. Finally, start the iLF/iME coprocessor using the appropriate command.

It is possible to write code with more than 128/256 instructions if the final instruction is a LoadInstBuf instruction with the parameters set toward another 128/256 instruction sequence.

**NOTE:** The final instruction of a sequence must always be the Endpgm() instruction; otherwise, an error is generated. The only exception is the LoadInstBuf(), which loads an additional instruction set in the program buffer.

Instructions written to a register or to memory must follow the format in [Table 14-11](#) and [Table 14-12](#). The Reserved bit must be set to 0, to pad the MSB to 32 bits.

**Table 14-11. iLF/iME PROGRAMBUFFERLINENMSB Register Detail**

31-23	22	21-17	16-12	11-7	6-2	1-0
Reserved	SW Breakpoint	OPcode	@field0	@field1	@field2	@field3

**Table 14-12. iLF/iME PROGRAMBUFFERLINENLSB Register Detail**

31-29	28-24	23-16	15-10	9-4	3	2	1-0
@field3	@field4	P0	P1	P2	P3	P4	P5

@fieldN indexes a data on the parameter stack. The number in @fieldN corresponds to the position of the corresponding data in the parameter stack.

PN parameters are passed directly in the OPcode.

The field 21:17 in the MSB word corresponds to the instruction OPcode.

Bit 22 in the MSB word indicates whether a break point is set for this instruction. If this bit is set to 1, the module reaches HALTED state at the end of this instruction.

[Section 14.3.5.2.2, LoadPStack\(\), iME Only](#), through [Section 14.3.5.2.5, EndPgm\(\)](#), describe the instructions common to iLF/iME. For descriptions of unique iLF/iME instructions, see [Section 14.3.6, iLF Module](#), and [Section 14.3.7, iME Module](#).

Instructions can be written either directly in the [iLF\\_PROGRAMBUFFERLINENLSBi](#) or [iME\\_PROGRAMBUFFERLINENLSBi](#) and [iLF\\_PROGRAMBUFFERLINENMSBi](#) or [iME\\_PROGRAMBUFFERLINENMSBi](#) registers or in the last 32K bytes of L2 memory and loaded into the iLF/iME register with the LoadInstBuf() instruction. Function parameters are passed directly in the OPcode of the instruction.

### 14.3.5.2.1 LoadPStack(), iLF Only

**Function:** Loads the parameter stack into the iLF local buffer. This is faster than writing directly to the iLF registers. This instruction supports two addressing modes: direct and indirect mode. In direct mode the SL2 offset is passed in the instruction. In indirect mode, the SL2 address is stored in the stack and the instruction includes an index to the stack word where the offset is stored.

**Parameters:**

- **SPAddr:** Index in the parameter stack pointing to the offset address from the SL2 start used to download the stack parameters from SL2 to the iLF internal register. Its value range is from 0 to 7.
- **AddressingMode:** This parameter can take two values:
  - 0 - Immediate addressing mode (address defined on P1...P5)
  - 1 - Indirect (address on stack pointed on @field0)
- **SL2 Address:** Offset in the SL2 start address where the array used to download the stack parameters from SL2 to the iLF internal registers is stored. Its value range is from 0 to 0xFFFF. Requirements: The address of the array must be 128-bit aligned. Used in direct addressing mode (AddressingMode = 1).

Table 14-13 shows the iLF LoadPStack() MSB format.

**Table 14-13. iLF LoadPStack() MSB Format**

### 14.3.5.2.2 LoadPStack(), iME Only

**Function:** Loads the parameter stack into the iME local buffer. This is faster than writing directly to the iME registers. The parameter stack must be in the last 32K bytes of the L2 memory. This instruction is similar to the LoadPStack() used in iLF (see Section 14.3.5.2.1).

**Parameters:**

- **SL2 Address:** Offset in the SL2 start address where the array used to download the stack parameters from SL2 to the iME internal registers is stored. Its value range is from 0 to 0xFFFF. Requirements: The address of the array must be 128-bit aligned.

Table 14-15 shows the iME LoadPStack() MSB format.

**Table 14-15. iME LoadPStack() MSB Format**

63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32

-	-	-	-	-	-	-	-	-	-	SL2 Address																					

### 14.3.5.2.3 LoadInstBuf()

**Function:** Loads the instruction buffer stored in the last 32K bytes of L2 memory into the iLF/iME local instruction buffer. Up to 128 instructions can be loaded with this instruction for the iLF module, and up to 256 instructions can be loaded for the iME module. For code containing more than 128 (iLF) or 256 (iME) instructions, the final instruction must be a LoadInstBuf() instruction with the parameters set toward another 128/256 instruction sequence.

**NOTE:** The final instruction of an instruction sequence must be the EndPgm() instruction; otherwise, an error is generated by the iLF/iME module when the sequence executes.

#### Parameters:

**SL2 source program address:** Offset from SL2 start address where the array used to download the instruction sequence into iLF/iME internal program memory is stored. Value: 0 to 0xFFFF. Requirements: The address of the array must be 128 bit-aligned.

**Number of instructions:** Number of instructions, minus one, to download

**Note:** The true number of instructions downloaded is a multiple of 4, so is equal to:

$$nb\_instr\_dl = 4 * \text{Int}[(nb\_instr+4)/4]$$

where Int[x] denotes the integer part of x.

Example: For nb\_instr = 0, 4 instructions are downloaded.

For nb\_instr = 3, 4 instructions are downloaded.

...

For nb\_instr = 127, 128 instructions are downloaded for iLF (if nb\_instr = 255, 256 instructions are loaded).

Table 14-17 shows iLF/iME LoadInstBuf() MSB format.

**Table 14-17. iLF/iME LoadInstBuf() MSB Format**

63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32

### 14.3.5.2.4 GenerateIT()

**Function:** Generates an interrupt to the sequencer and/or to the DSP megamodule. For more information about interrupts, see Section 14.3.4.2, *Sequencer Interrupts*, for sequencer interrupts and Section 14.3.11.5.3, *Interrupt Handler*, for interrupts toward the DSP megamodule.

**Parameters:** This function does not take any parameters.

Table 14-19 shows iLF/iME GenerateIT() MSB format.

**Table 14-19. iLF/iME GenerateIT() MSB Format**

63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32

**14.3.5.2.5 EndPgm()**

**Function:** Indicates completion of program execution; permits the iLF/iME to go to COMPLETED state without error generation

**Parameters:** This function does not take any parameter.

Table 14-21 shows iLF/iME EndPgm() MSB format.

**Table 14-21. iLF/iME EndPgm() MSB Format**

63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32

**14.3.5.3 Parameters in L2**

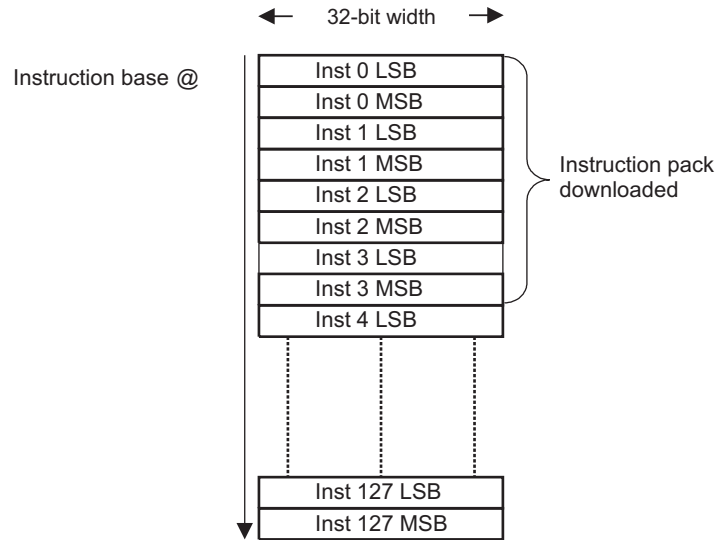

Parameters addressing a block of data in the SL2 space are given as an offset from the SL2 start address. This is true for parameters inside instructions and for parameters stored in the parameter stack.

**14.3.5.3.1 Instructions**

An instruction sequence can be stored in the last 32K bytes of L2 memory. This sequence is loaded in the iLF/iME with a load instruction followed by an end-program instruction. All iLF/iME instructions are 55 bits wide and padded with 0 on the MSB to reach 64 bits. Then, one 64-bit instruction is split into two 32-bit words to be stored in the DSP megamodule memory.

Figure 14-21 shows the instruction sequence format in L2 memory that must be used with the LoadInstBuf() iLF/iME instruction.

**Figure 14-21. iLF/iME Instruction Sequence Format in L2 Memory**

iva22-021

When the LoadInstBuf() command is performed from the iLF/iME side, the memory interface reads data in the L2 by 256-bit access.

Thus, the iLF/iME reads instructions by a burst of four instructions. The LoadInstBuf() instruction can load up to 128 instructions for the iLF coprocessor and up to 256 instructions for the iME coprocessor, corresponding to the sizes of the instruction buffers of the iLF and iME modules.

When instructions are loaded in the iLF/iME, they can be read or written (written only if iLF/iME is not in EXECUTING state) in the registers. These instructions are mapped on the [iLF\\_PROGRAMBUFFERLINENLSBi](#) or [iME\\_PROGRAMBUFFERLINENLSBi](#) and [iLF\\_PROGRAMBUFFERLINENMSBi](#) or [iME\\_PROGRAMBUFFERLINENMSBi](#) registers, from offset 0x040 to offset 0x43C from an iLF base address, and from offset 0x040 to offset 0x83C from an iME base address. For more information about mapping instruction registers, see [Section 14.5, IVA2.2 Subsystem Register Manual](#).

### 14.3.6 iLF Module

The IVA2.2 subsystem includes an iLF module for performing hardware filtering for video coding and decoding. This module performs loop filtering for video code/decode operations (codecs) without DSP megamodule processing power. This hardware accelerator is considered a programmable coprocessor, as the main DSP megamodule or the sequencer can load an instruction buffer in the module, start the instruction sequence, and then the iLF module is autonomous until the end of the sequence.

The iLF performs loop filtering for four codecs:

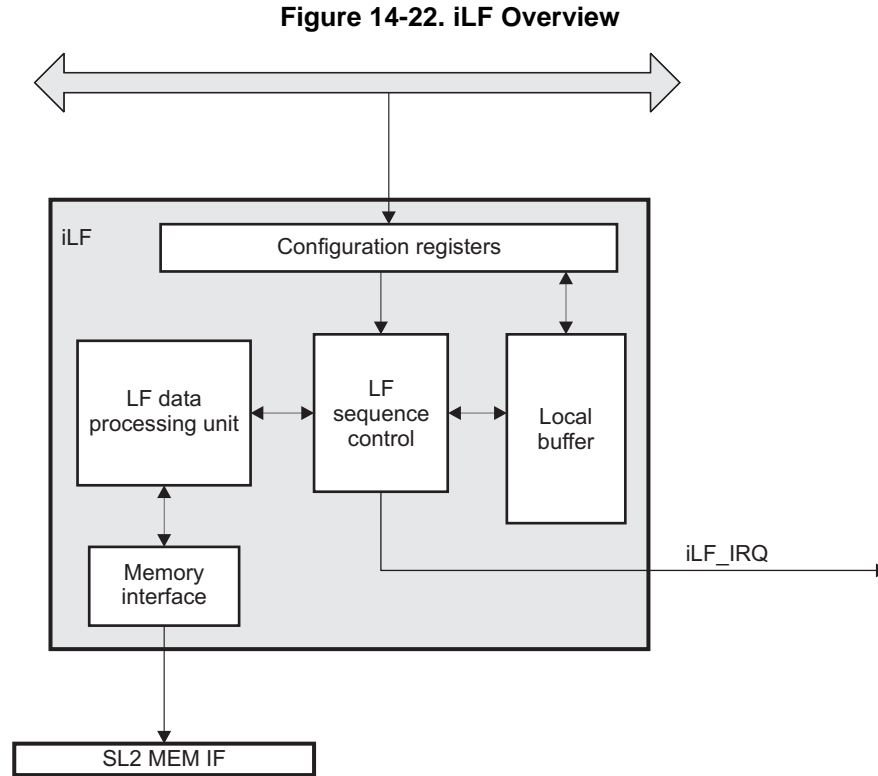

- H264
- H263-MPEG4
- WMV9
- REAL8 and 9

The iLF has two main interfaces:

- Slave on the video and sequencer local interconnect. This interface allows the sequencer and the DSP megamodule to access the iLF register in read/write mode. To access the iLF module registers through the local interconnect, the EFI instructions must be used on the DSP megamodule.
- Master on the SL2 memory interface. This interface allows the iLF to access data stored in the last 32K bytes of the L2 flat memory. The DSP megamodule or the sequencer can exchange configuration/data to/from the iLF through the last 32K bytes of L2 flat memory.

The iLF module can generate an interrupt to the sequencer and the DSP megamodule on completion or on error. For information about sequencer interrupts, see [Section 14.3.4.2, Sequencer Interrupts](#). For information about video accelerator and sequencer interrupts toward the DSP megamodule, see [Section 14.3.11.5, Video Accelerator/Sequencer SYSC](#).

Figure 14-22 is an overview of the iLF module.

iva22-022

### 14.3.6.1 iLF Control

iLF control is similar to iME control, and is described in [Section 14.3.5, iLF and iME Common Part](#).

#### 14.3.6.1.1 Instruction Set

The iLF module provides a reduced instruction set to load, prepare, and compute data. [Table 14-23](#) lists the instructions available in the iLF.

**Table 14-23. iLF Instruction Set List**

Instruction	Parameters	Parameter Type	OPcode (hexa)
ParseEdge()	Configuration data (see <a href="#">Section 14.3.6.3.2.2, Parse-Edge Parameter Stack Data</a> ) MBClips1 (content of parameter set to 0 if not used) MBClips2 (content of parameter set to 0 if not used) Edge index (from 0 to 15) Block number (from 0 to 15) Parsing parameters stored in the parameter stack from address 8 to 15	Stack index, 5-bit Stack index, 5-bit Stack index, 5-bit Parameter, 8-bit Parameter, 6-bit	0x01
LoadEFPT()	Read address (in L2. Offset from the SL2 start address, aligned to 128 bits)	Stack index, 5-bit	0x0b
LoadPStack()	Stack index where SL2 offset is stored Parameter to specify whether direct or indirect load used Stack offset in SL2 (in L2. Loads 128 bytes starting at 128 bits-aligned location)	Stack index, 5-bit Parameter, 8-bit Parameter, 16-bit	0x0a

**Table 14-23. iLF Instruction Set List (continued)**

Instruction	Parameters	Parameter Type	OPcode (hexa)
LoadInstBuf()	Program start @ (in L2. Offset from the SL2 start address, 16-bit, aligned on a 16-byte boundary) Number of instructions (instructions must be aligned in 64-bit bins, padded with zeroes toward the MSBs)	Parameter, 16-bit Parameter, 8-bit	0x10
FilterEdge()	Base address of the data block (in L2. Offset from the SL2 start address), absolute, 16-bit Opcode (0=Filter, 1 = Load&Filter, 2 = Filter&Storeback, 3 = LoadFilter&Storeback) <sup>(1)</sup> Filter parameters stored in the parameter stack from address 16 to 31	Stack index, 5-bit Parameter, 2-bit	0x04
Endpgm()	None (indicates program execution completion)		0x1f
GenerateIT()	None (triggers interrupt from inside the program, if IT enabled)		0x1e

<sup>(1)</sup> Instruction format is described in the iLF/iME command control. For more information, see [Section 14.3.6.2.2, FilterEdge\(\)](#).

#### 14.3.6.1.2 Commands

For information about iLF commands, see [Section 14.3.5.1.1, Commands](#).

#### 14.3.6.1.3 Execution States

For information about iLF execution states, see [Section 14.3.5.1.2, Execution States](#).

#### 14.3.6.2 Instructions

The instructions described in [Section 14.3.6.2.1](#) through [Section 14.3.6.2.3](#) can be either directly written in the `iLF_PROGRAMBUFFERLINENLSBi` and `iLF_PROGRAMBUFFERLINENMSBi` registers or written in the last 32K bytes of L2 memory and loaded into the iLF register with the `LoadInstBuf()` instruction. The function parameters are passed directly in the OPcode of the instruction.

For instructions common to the iLF and iME coprocessors-`LoadPStack()`, `LoadInstBuf()`, `GenerateIT()`, `EndPgm()`-see [Section 14.3.5.2, Instruction Set](#).

Each instruction is stored in a set of two 32-bit registers. There are 128 sets of two instruction registers in the iLF. The iLF can buffer 128 instructions at a time. It is possible to write code with more than 128 instructions if the final instruction is a `LoadInstBuf` instruction with the parameters set toward another 128-instruction sequence in SL2 memory.

### 14.3.6.2.1 ParseEdge()

**Function:** Parses the edge between pixel blocks; prepares the filtering pass

**Parameters:**

- **CFG:** Index in the parameter stack pointing to the configuration. Value: From 0 to 7.
- **MBClips1idx:** Index in the parameter stack pointing to the first set of MBClips (REAL9, 0 when not used). Value: From 0 to 7.
- **MBClips2idx:** Index in the parameter stack pointing to the second set of MBClips (REAL9, 0 when not used). Value: From 0 to 7.
- **Edge Index:** Index of the current edge in the parameter stack. Value: From 0 to 15.
- **Block Number:** Number of the block 4\*4 containing the current edge in the macroblock. Value: From 0 to 15.

Table 14-24 shows the iLF ParseEdge() MSB format.

**Table 14-24. iLF ParseEdge() MSB Format**

63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32

### 14.3.6.2.2 FilterEdge()

**Function:** Operates the filtering processing. This function operates on data stored in L2 and stores the processed data back in L2 memory.

**Parameters:**

- **SAddress:** Index in the parameter stack pointing to the offset address from the SL2 start that contains the input/write buffer windows to filter. Value: From 0 to 7.
- **Opcode:** Specifies whether the SL2 area must be loaded into iLF internal memory (iLF input/write buffer) before filtering and/or whether the internal memory must be stored in SL2 after filtering. Value: 0 to 3 with the following meanings:
  - FILTER 0x0
  - LOAD\_FILTER 0x1
  - FILTER\_STOREBACK 0x2
  - LOAD\_FILTER\_STOREBACK 0x3

Table 14-26 shows the iLF FilterEdge() MSB format.

**Table 14-26. iLF FilterEdge() MSB Format**

63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32

### 14.3.6.2.3 LoadEFPT()

**Function:** Loads the edge-level filter parameters table (EFPT) in the iLF local buffer.

**Parameters:**

- **SAddress:** Index in the parameter stack pointing to the address of the EFPT in the SL2 space (offset from the SL2 start address). Requirements: The address of the array must be 128-bit-aligned.

Table 14-28 shows the iLF LoadEFPT() MSB format.

**Table 14-28. iLF LoadEFPT() MSB Format**

63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32

### 14.3.6.3 Parameters

#### 14.3.6.3.1 Instructions

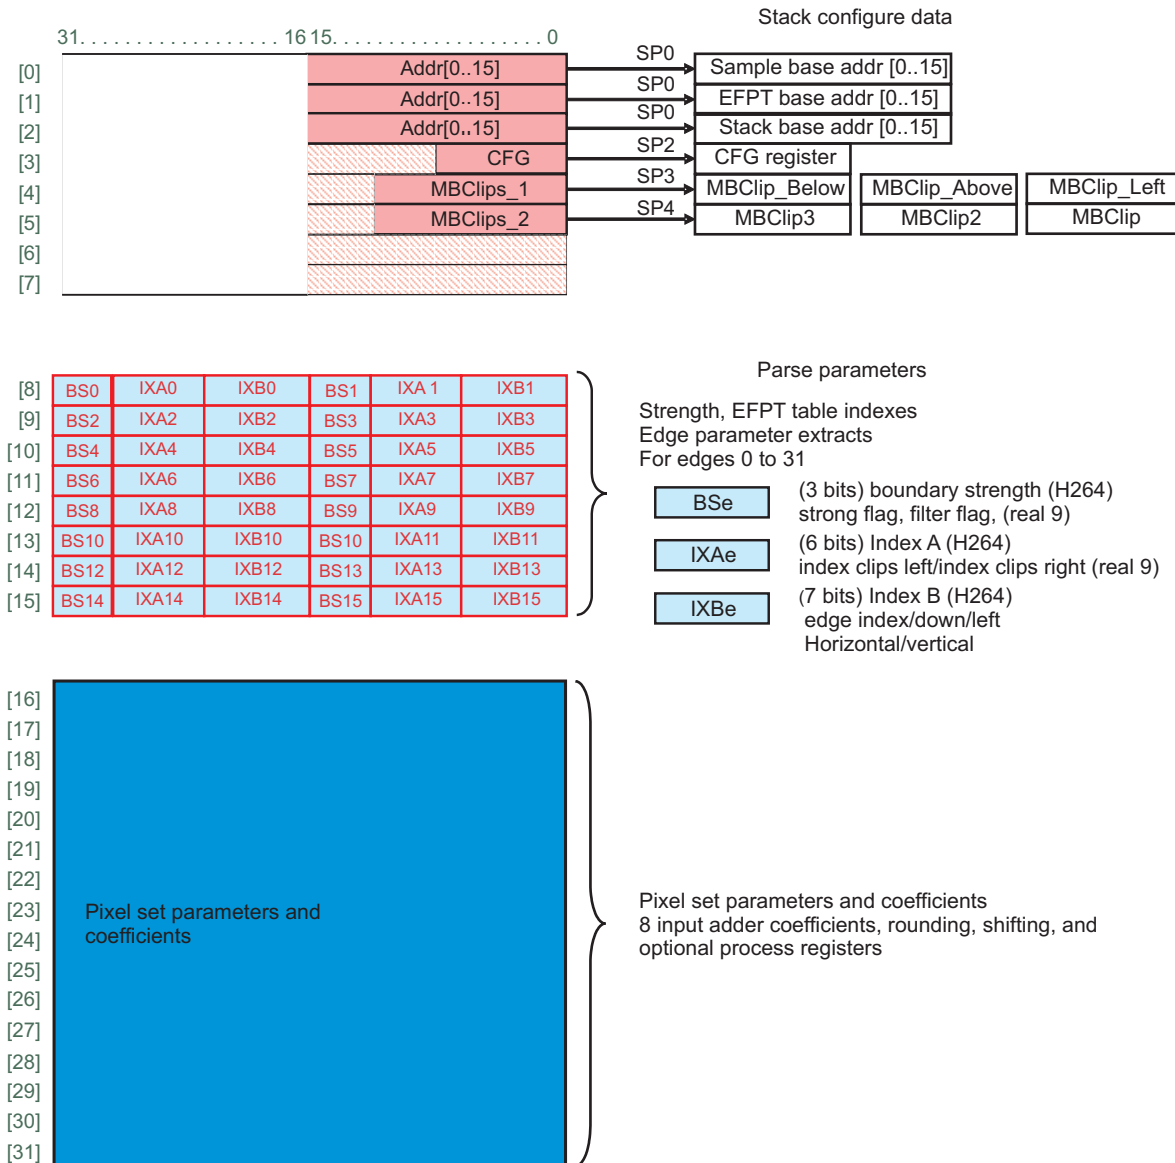

Instruction format in L2 is the same for the iLF and iME modules. For information about formatting instructions in L2, see Section 14.3.5.3.1, *Instructions*.

#### 14.3.6.3.2 Parameter Stack

Figure 14-23 is an overview of the parameter stack stored in L2, consisting of three parts:

- **Stack configure data:** Includes addresses, MB configure, and the edge-configure section, which is addressed with the @fieldN parameters in the different instructions. Stack configure data are stored from word 0 to word 7. The configuration of this stack section is not fixed; each field is indexed with an instruction parameter when it must be used. These parameters are 32 bits wide in L2 memory, but when they are downloaded to the iLF internal memories, a mask is applied on the 16-MSB section of the word; therefore, only the 16 LSBs must be used.
- **Parse parameters:** Used by the ParseEdge() instruction. Parse parameters are stored from word 8 to word 15 and are 32-bit words. They allow configuration of the filter for the filtering parts. They are fixed parameters for a macroblock.
- **Pixel set parameters and coefficients:** Used by the FilterEdge() instruction. They are stored from word 16 to word 31 and are 32-bit words. These parameters allow filtering to be performed. They are fixed parameters

Figure 14-23. iLF Stack Parameter Format

iva22-023

### 14.3.6.3.2.1 Stack Configure Data

Stack configure data occupy word 0 to word 7 of the parameter stack. In this section of the stack, all words are 32 bits, but only the lower 16 bits are used. When the parameter stack is downloaded to iLF internal memory, a mask is applied on the upper 16 bits of the stack configure data words; consequently, all data stored in the stack configure data section are 16 bits wide, stored in the lower part of a 32-bit word.

Data stored in this section of the parameter stack are not on a fixed word; they are referenced through an index inside the instruction. The value of this index corresponds to the word where the data is stored.

Table 14-30 shows how data are stored in the stack configure data section of the parameter stack.

**Table 14-30. iLF Stack Configure Data Format**

@	Pointer to @ stack Related @fieldx points to any parameter stack address from range 0 to 7	Description	Std	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

3				H263	PQUANT															
				REAL9	Reserved															
4	ParseEdge()	@field3	Clips1	H264	Reserved															
				WMV9 H263	Reserved															
5				REAL9	MBClip below				MBClip above				MBClip left							
6	ParseEdge()	@field4	Clips2	H264	Reserved															
				WMV9 H263	Reserved															
7				REAL9	MBClip3				MBClip2				MBClip							

These eight words can store five types of data:

- Sample base address: Used in the FilterEdge() instruction to indicate the offset from the SL2 start of the input/write buffer windows, stored in the last 32K bytes of shared L2 memory, for the filter computation. This address must be 128-bit-aligned. It is coded on 16 bits and must reference the first byte of the first block in the input/write buffer windows. For more information about the input/write buffer, see [Section 14.3.6.3.7, Input/Write Buffer](#).
- EFPT base address: Used in the LoadEFPT() instruction, this is an offset (from the SL2 start address) that indicates the start of the EFPT in the last 32K bytes of L2 shared memory. This address must be 128-bit-aligned. The EFPT table is used only for REAL9 and H264 video codecs. The value of this table is given in [Section 14.3.6.3.3, Loop-Filter Parameter Stack and EFPT for H264](#), for H264 and in [Section 14.3.6.3.6, Loop-Filter Parameter Stack and EFPT for REAL9](#), for REAL9.
- Stack base address: Used in the LoadPStack() instruction, this is an offset (from the SL2 start address) that indicates the start of the parameter stack in the last 32K bytes of the L2 shared memory. This address must be 128-bit-aligned.
- CFG: Configures the iLF for the filtering operation; composed of three parts:
  - CMR (condition mode) detailing the codec currently filtered. For codec codes, see [Table 14-31](#).
  - LUMA detailing if the block filtered is a LUMA block (1 if LUMA, 0 if other)
  - Slice A and Slice B are used to compute index A and index B and take the values alpha and beta in the threshold table. Range value from -6 to 6 (H264 standard).
  - PQUANT contains quantization data, REAL specific value.
- Clips1 and Clips2: REAL9 specific; they contain the MBClip value.

[Table 14-31](#) shows the CMR code corresponding to the codec supported by the iLF coprocessor.

**Table 14-31. iLF CMR Code**

Codec	Code
H264	0x0
H263	0x1
REAL9	0x2

**Table 14-31. iLF CMR Code (continued)**

Codec	Code
WMV9	0x3

**NOTE:** A data type can have multiple instances in the stack configure data, such as multiple sample base addresses for loading different parts of a macroblock for filtering.

#### 14.3.6.3.2.2 Parse-Edge Parameter Stack Data

Parse-edge parameter data are stored in the parameter stack from word 8 to word 15. All the data blocks are 16 bits wide, so there are 16 parse-edge blocks corresponding to 16 different edges. Each block of data describes the parameter required for an edge. Data stored in these blocks are codec-dependent and are described in the codec specification.

The 16 edge blocks are referenced by the EdgeIndex parameters of the ParseEdge() instruction.

The Edge\_HV bit indicates whether the filtered edge is horizontal or vertical; 0 corresponds to a horizontal edge and 1 to a vertical edge.

The BS value for H.264 corresponds to Luma or Chroma first blocks. The BSB value for H.264 corresponds to Chroma second blocks.

After ParseEdge() and before FilterEdge(), the [iLF\\_PARSEDATAREG1](#) register is set with the value extracted from Parse-Edge Parameter Stack Data.

[Table 14-32](#) shows the parse-edge parameter data format and the correspondence between the index and parse-edge block data.

**Table 14-32. iLF Parse-Edge Parameter Stack Data**

@	Edge Index	Std	3	3	2	2	2	2	2	2	2	2	1	1	1	1	1	1	1	1	9	8	7	6	5	4	3	2	1	0

#### 14.3.6.3.4 Loop-Filter Parameter Stack for H263

Table 14-35 lists the values of the loop-filter parameters stored in the parameter stack for the H263 video codec.

**Table 14-35. iLF Loop Filter Parameter Stack for H263**

Word	Value	Word	Value
16	0x01 A8 40 00	24	0x34 C9 31 95
17	0x00 06 A1 04	25	0x24 CD 3F 6E
18	0x68 C3 13 34	26	0x24 CD 3E 7B
19	0x68 C6 A1 00	27	0x34 C9 30 00
20	0x00 00 00 00	28	0x03 04 04 A4
21	0x00 00 00 00	29	0x48 48 48 48
22	0x80 40 20 00	30	0x58 58 58 58
23	0x10 84 20 A2	31	0x00 46 60 01

There is no EFPT table for the MPG4 codec.

#### 14.3.6.3.5 Loop-Filter Parameter Stack for WMV9

Table 14-36 lists the values of the loop-filter parameters stored in the parameter stack for the WMV9 video codec.

**Table 14-36. iLF Loop-Filter Parameter Stack for WMV9**

Word	Value	Word	Value
16	0x01 A8 40 00	24	0x32 C8 B1 95
17	0x00 06 A1 04	25	0x22 CC BF 6E
18	0x68 C3 13 34	26	0x22 CC BE 7B
19	0x68 C6 A1 00	27	0x32 C8 B0 00
20	0x00 00 00 00	28	0x03 04 04 A4
21	0x00 00 00 00	29	0x48 48 48 48
22	0x80 40 A0 00	30	0x58 58 58 58
23	0x12 84 A0 A2	31	0x00 46 60 01

There is no EFPT table for the WMV9 codec.

#### 14.3.6.3.6 Loop-Filter Parameter Stack and EFPT for REAL9

Table 14-37 lists the values of the loop-filter parameters stored in the parameter stack for the REAL9 video codec.

**Table 14-37. iLF Loop-Filter Parameter Stack for REAL9**

Word	Value	Word	Value
16	0x0C 17 18 00	24	0x72 42 D1 A4

### 14.3.6.3.7 Input/Write Buffer

The iLF module contains an input/write buffer that retrieves pixel data stored in the last 32K bytes of the L2 flat memory by the memory interface, and stores them in an iLF local buffer during the pixel filtering pass. There is no dedicated command to load and/or write to the iLF input/write buffer. The action is performed with an option passed in the FilterEdge() instruction. The second parameters in the OPcode instruction contain this option. [Table 14-39](#) shows the different value for the second parameters.

**Table 14-39. iLF FilterEdge() Load and Store Parameter**

Name	OPcode	Description
FILTER	0x0	Filter data already on input/write buffer.
LOAD_FILTER	0x1	Load input/write buffer from L2 memory, then filter the data in the buffer.
FILTER_STOREBACK	0x2	Filter data already in the input/write buffer, then write the iLF input/write buffer to L2 memory.
LOAD_FILTER_STOREBACK	0x3	Load the input/write buffer from L2 memory, filter the data in the buffer, then write back the iLF input/write buffer to L2 memory.

The memory interface of the iLF coprocessor retrieves and/or stores data from/to the last 32K bytes of the L2 memory, depending on the OPcode passed to the FilterEdge() instruction. The input/output (I/O) buffer can store 2 rows of 5 pixel matrices (4 x 4). Ultimately, the iLF can filter 8 vertical edges or 4 horizontal edges with a single load.

The iLF input/write buffer processes a macroblock with 2 windows for a vertical edge and 4 windows for a horizontal edge.

The FilterEdge() instruction contains a stack pointer address (SPAddress) that is a link to a 16-bit word contained in the parameter stack (for more information about the parameter stack, see [Section 14.3.6.3.2, Parameter Stack](#)). This address is an offset from the SL2 start pointing toward the start of the input/write buffer windows. It must be 128-bit-aligned. It is used when a load or a store is ordered by the FilterEdge() instruction.

[Figure 14-24](#) shows the pixel data format and order in memory, and the input/write buffer window. There are two numbers for blocks; the upper number corresponds to the location of the block in L2 memory, the lower number corresponds to the index of the block in a macroblock.

Figure 14-24. iLF Pixel Format in L2 Memory

iva22-024

The iLF has an internal 160-bit-wide buffer and can only perform 256-bit accesses to SL2. Each time the FilterEdge() instruction is executed to load memory from SL2 into iLF internal memories, iLF loads 8 lines of 32 bytes (only 20 bytes are useful). Figure xx shows how data is organized in SL2 and iLF internal memory.

Figure 14-25. iLF Internal Pixel Format

iva22\_swpu108-050

### 14.3.6.3.8 Parse-Edge Parameters

The block-number parameter in the ParseEdge() instruction indicates which edge must be parsed to be filtered. This number depends on the current windows in the input/write buffer and on the edge type (horizontal or vertical). Figure 14-26 shows the position of the 15 edges in the input/write buffer. For more information about the ParseEdge() parameters, see Section 14.3.6.3.2.2, *Parse-Edge Parameter Stack Data*.

Figure 14-26. iLF Edge Numbering

### 14.3.7 iME Module

The IVA2.2 subsystem contains an iME module that estimates hardware motion for video coding, according to multiple video codecs, without using DSP megamodule processing power. This hardware accelerator is considered a programmable coprocessor, because the main DSP megamodule or the sequencer can load an instruction buffer in the module, start the instruction sequence, and then the iME module is autonomous until the end of the sequence.

The iME is not codec-dependent; it is not designed for a given motion estimation algorithm (like step-search).

The iME interpolates motion estimates for three codecs:

- H264
- H263-MPEG4
- WMV9

The iME has two interfaces:

- Slave on the local interconnect. This interface gives the sequencer and the DSP megamodule access to the iME register in read/write mode. To access the iME module registers, EFI instructions must be used on the DSP megamodule.
- Master on the SL2 memory interface. This interface gives the iME access to data stored in the last 32K bytes of L2 flat memory. The DSP megamodule or the sequencer can exchange configuration/data to/from the iME through the last 32K bytes of L2 flat memory.

The iME module can generate an interrupt to the sequencer and the DSP megamodule, on completion or on error. For more information about sequencer interrupts, see Section 14.3.4.2, *Sequencer Interrupts*. For more information about video accelerator and sequencer submodule interrupts toward the DSP megamodule, see Section 14.3.11.5.3, *Interrupt Handler*.

Figure 14-27 is an overview of the iME module.

Figure 14-27. iME Overview

iva22-026

### 14.3.7.1 iME Control

The iME control is similar to the iLF control, and is detailed in [Section 14.3.5, iLF and iME Common Part](#).

#### 14.3.7.1.1 Instruction Set

The iME provides a reduced instruction set to load, prepare, and compute data. [Table 14-40](#) lists the instructions available in the iME.

Table 14-40. iME Instruction Set

Instruction	Parameters	Parameter Type	OPcode (hexa)
ErrorCalc()	Search window base @ Search start @ OffsetH (horizontal, local offset) OffsetV (vertical, local offset) Motion vector parameters Search window line length (in bytes) Offset code Error number Use best-match information (Y, N).	@field0 @field1 @field2 @field3 @field4 P0 P1 P2 P4	0x0000
SaveErrs()	Save address, 16-bit (offset from SL2 start address. Saves all errors in the error-storage table in 2 contiguous 256-bit-aligned words).	P1-P5	0x02
SaveStatus()	Save address, 16-bit (offset from SL2 start address. Saves the best-match error in one 128-bit-aligned word).	P1-P5	0x03
RestorErrs()	Restore address (offset from SL2 start address. Restores all errors in the error-storage table, from 2 contiguous 256-bit-aligned words).	P1-P5	0x04
Mcompare () (supports only comparison of 5 to 16 errors)	Motion vector parameters (only MVtype is used) Offset Error number start, in error-storage table Number of errors to compare ( = 5 errors) Include last best match (Y, N). Compare every N errors (N = 1, 2, 4, 8).	@field4 P0 P1 P2 P4 P5	0x05

**Table 14-40. iME Instruction Set (continued)**

Instruction	Parameters	Parameter Type	OPcode (hexa)
Mcompare2 () (supports comparison of only 2 errors)	Motion vector parameters (only MVtype is used) Offset Error number start, in error-storage table Include last best match (Y, N). Compare every N errors (N = 1, 2, 4, 8).	@field4 P0 P1 P4 P5	0x06
Mcompare4 () (supports comparison of only 4 errors)	Motion vector parameters (only MVtype is used) Offset Error number start, in error-storage table Include last best match (Y, N). Compare every N errors (N = 1, 2, 4, 8).	@field4 P0 P1 P4 P5	0x07
ClearStatus()			0x08
LoadRefBlk()	Load start @ (offset from SL2 start address, aligned on a 16-byte boundary)	P1-P5	0x09
LoadPStack()	Stack address (offset from SL2 start address, loads 128 bytes starting at a 128-bit-aligned location)	P1-P5	0x0a
LoadRefBlk_Ind()	Load start @	@field0	0x0b
SaveBestMatch()	Parameter stack destination index	@field0	0x0c
RestoreBestMatch()	Parameter stack source index	@field0	0x0d
ExitOnMinReached()	None (acts as EndPgm() if AbsMinReached is set, otherwise act as nop)		0x0e
WaitOnSignal()	None (waits for OCP sync command)		0x0f
LoadInstBuf()	Program start @ (offset from SL2 start address, 16-bit, aligned on a 16-byte boundary) Number of instructions (instructions must be aligned into 64-bit bins, padded with zeroes towards the MSBs)	P1-P5 P0	0x10
Memcpy()	Block source start @ (offset from SL2 start address, 16-bit, aligned to a 16-byte boundary) Block destination start @ (offset from SL2 start address, 16-bit, aligned to a 16-byte boundary) Number of 32 bytes transferred (copy of Nx32 bytes from source to destination, in L2)	@field0 @field1 P0	0x11
LoadMVCT()	Load address (offset from SL2 start address. Loads both X and Y MVC tables, from 2 contiguous 256-bit-aligned words).	P1-P5	0x12
Interpolate()	Search window base @, absolute Filter start @ Store @ (aligned to a 16-byte boundary) Line size Include last best-match info (Y, N) Block size (8x8, 16x16, 24x24)	@field0 @field1 @field3 P0 P4 P5	0x13 ~ 0x17
GenerateIT()	None (triggers interrupt from inside the program, if IT enabled)		0x1e
Endpgm()	None (indicates program execution completion)		0x1f

Instruction format is described in the iLF/iME command control. For more information, see [Section 14.3.5.1.1, Commands](#).

#### 14.3.7.1.2 Commands

The iME hardware accelerator uses all the generic commands described in [Section 14.3.5.1.1, Commands](#), plus a sync() command. The sync() command is described in [Table 14-41](#).

**Table 14-41. iME Specific Command**

Command	Description	Code
sync()	This command resets the <code>iME_CONFIGREG[6]</code> WAITING_FOR_SYNC_SIGNAL bit if it is already set; otherwise, the <code>iME_CONFIGREG[5]</code> SYNC_SIGNAL_SET bit is set, and is then reset when the WaitOnsignal() instruction is decoded.	0x7

### 14.3.7.1.3 Execution States

For information about iME commands, see [Section 14.3.5.1.1, Commands](#).

### 14.3.7.2 Instructions

The instructions described in [Section 14.3.7.2.1, ErrorCalc\(\)](#), to [Section 14.3.7.2.16, Interpolate\(\)](#), can be either written directly in the `iME_PROGRAMBUFFERLINENLSBi` and `iME_PROGRAMBUFFERLINENMSBi` registers or written in the last 32K bytes of L2 memory and loaded into the iME register by the `LoadInstBuf()` instruction. The function parameters are passed directly in the OPcode of the instruction.

For instructions common to the iLF and iME coprocessors-`LoadPStack()`, `LoadInstBuf()`, `GenerateIT()`, `EndPgm()`-see [Section 14.3.5.2, Instruction Set](#).

Each instruction is stored in two 32-bit registers. There are 256 sets of two instruction registers in the iME. The iME can buffer 256 instructions at a time. Code with more than 256 instructions can be written if the final instruction is a `LoadInstBuf` with the parameters set toward another 256 instruction sequence in SL2 memory.

#### 14.3.7.2.1 ErrorCalc()

**Function:** Calculates the error between the reference block and a block in the search area. The result of this instruction is an error value and an address corresponding to the block compared in the search area. These two results are stored in a single 32-bit word in the error table. The index in the error table is determined by the `ErrorNum` parameter. The `MVParams` describe how the two blocks are compared. If a parallel motion vector is used, multiple errors and addresses are generated. When two errors are computed in parallel, they are stored contiguously starting at an even location index. When four errors are computed in parallel, errors are stored contiguously starting at a multiple-of-four location index

**Parameters:**

- **WinStartAddr:** Index in the parameter stack pointing to the offset address from the SL2 start of the upper left pixel of the search window in SL2 memory
- **SearchStartAddr:** Index in the parameter stack pointing to the upper left pixel of the current block in the current search window
- **OffsetH:** Index in the parameter stack pointing to the horizontal offset (expressed in bytes) unsigned
- **OffsetV:** Index in the parameter stack pointing to the vertical offset (expressed in bytes) unsigned
- **MVParams:** Index in the parameter stack pointing to the motion vector parameters
- **SearchWinLineLength:** Line length of the search window expressed in pixels. Value = 0 to 255.
- **OffsetCode:** Code of the offset to determine which neighbor block is to be processed. Value = 0 to 8, defined as follows:

CENTRAL	0x0
UP_LEFT	0x1
UP	0x2
UP_RIGHT	0x3
LEFT	0x4
RIGHT	0x5
DOWN_LEFT	0x6
DOWN	0x7
DOWN_RIGHT	0x8

- **ErrorNum:** Index of the error stored in the error table. Value = 0 to 15.
- **UseBestMatchInfo:** Initial address flag; if it equals 0, the current block address is based on the `WindowStartAddress` and `SearchStartAddress` parameters. If it equals 1, the address is based on the address of the block having the best error. It is saved in the iME internal register `LatestError`.

[Table 14-42](#) shows the iME `ErrorCalc()` MSB format.

**Table 14-42. iME ErrorCalc() MSB Format**

63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32

OffsetV			MVParams				SearchWinLineLength				OffsetCode				ErrNum				-	Use Bes tMa tchl nfo	-	-									

**14.3.7.2.2 SaveErrs()**

**Function:** Stores the iME internal error table in shared L2 memory. The L2 address is given through a parameter. iME internal errors are in a 16-entry register file ([iME\\_ERRORTABLEj](#)) containing final 16-bit errors and associated 16-bit addresses.

**Parameters:**

- **SL2Address:** Offset in the SL2 space (from the SL2 start address) of the array used to store the iME internal error table. Value = 0 to 0xFFFF. The address of the SL2 array must be 128-bit-aligned.

Table 14-44 shows the iME SaveErrs() MSB format.

**Table 14-44. iME SaveErrs() MSB Format**

**14.3.7.2.3 SaveStatus()**

**Function:** Stores the iME best-match address in the shared L2 memory. The L2 address is given through a parameter.

**Parameters:**

- **SL2Address:** Offset in the SL2 space (from the SL2 start address) of the array used to store iME status values. Value = 0 to 0xFFFF. The address of the SL2 array must be 128-bit-aligned.

Table 14-46 shows the iME SaveStatus() MSB format.

#### 14.3.7.2.4 RestoreErrs()

**Function:** Restores the iME internal error table from shared L2 memory. The L2 address is given through a parameter. iME internal errors are in a 16-entry register file ([iME\\_ERRORTABLEj](#)) containing final 16-bit errors and associated 16-bit addresses.

**Parameters:**

- **SL2Address:** Offset in the SL2 space (from the SL2 start address) of the array used to download the error table into iME internal registers. Value = 0 to 0xFFFF. The address of the SL2 array must be 128-bit-aligned.

Table 14-48 shows the iME RestoreErrs() MSB format.

**Table 14-48. iME RestoreErrs() MSB Format**

#### 14.3.7.2.5 Mcompare ()

**Function:** Compares 5 to 16 errors stored in the iME error table and stores the best match (the smallest error) in the IVA.[iME\\_LATESTERRORS](#) register with the corresponding address (IVA.[iME\\_LATESTERRORS](#) has the same format as the error table). Before performing the comparison between errors stored in the error table, a motion vector cost can be applied to errors. If the comparison includes the IVA.[iME\\_LATESTERRORS](#) register, the IncludeLastBest parameter must be set to 1. This instruction should be explicitly executed after 16 ErrorCalc() instructions.

**Parameters:**

- **MVType:** Index in the parameter stack pointing to the motion vector type. Value = 0 to 32.
- **Offset:** Offset for motion vector cost functionality. Value = 0 to 255.
- **ErrorStartNum:** Index of the first error to compare in the iME error table. Value = 0 to 14.
- **NumOfErrs:** Number of errors to compare, excluding the last best error. Value must be at least 5.
- **IncludeLastBest:** If it equals 0, it compares the errors to only the error table values. If it equals 1, it compares the errors to the best error already found. Value = 0 or 1.
- **CompareEvery:** Error table stride code. The stride is derived from the CompareEvery parameter by the relation  

$$\text{stride} = 1 \ll \text{CompareEvery}$$

The values possible for this parameter are: 0, 1, 2, or 3, indicating a comparison to 1, 2, 4, or 8 errors, respectively.

Table 14-50 shows the iME MCompare() MSB format.

**Table 14-50. iME MCompare() MSB Format**

63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32

### 14.3.7.2.6 Mcompare2 ()

**Function:** Compares two errors stored in the iME error table and stores the best match (the smallest error) in the IVA.[iME\\_LATESTERRORS](#) register with the corresponding address (IVA.[iME\\_LATESTERRORS](#) has the same format as the error table). Before performing the comparison between errors stored in the error table, a motion vector cost can be applied to errors. If the comparison includes the IVA.[iME\\_LATESTERRORS](#) register, the IncludeLastBest parameter must be set to 1.

#### Parameters:

- **MVType:** Index in the parameter stack pointing to the motion vector type. Value = 0 to 32.
- **Offset:** Offset for motion vector cost functionality. Value = 0 to 255.
- **ErrorStartNum:** Index of the first error to compare in the iME error table. Value = 0 to 14.
- **IncludeLastBest:** If it equals 0, it compares the errors to only the error table values. If it equals 1, it compares the errors to the best error already found. Value = 0 or 1.
- **CompareEvery:** Error table stride code. The stride is derived from the CompareEvery parameter by the relation

stride = 1 << CompareEvery.

The values possible for this parameter are: 0, 1, 2, or 3, indicating a comparison to 1, 2, 4, or 8 errors, respectively.

Table 14-52 shows the iME MCompare2() MSB format.

**Table 14-52. iME MCompare2() MSB Format**

### 14.3.7.2.7 Mcompare4 ()

**Function:** Compares four errors stored in the iME error table and stores the best match (the smallest error) in the IVA.iME\_LATESTERRORS register with the corresponding address (IVA.iME\_LATESTERRORS has the same format as the error table). Before performing the comparison between errors stored in the error table, a motion vector cost can be applied to errors. If the comparison includes the IVA.iME\_LATESTERRORS register, the IncludeLastBest parameter must be set to 1.

**Parameters:**

- **MVType:** Index in the parameter stack pointing to the motion vector type. Value = 0 to 32.
- **Offset:** Offset for motion vector cost functionality. Value = 0 to 255.
- **ErrorStartNum:** Index of first error to compare in iME error table. Value = 0 to 14.
- **IncludeLastBest:** If it equals 0, it compares the errors to only the error table values. If it equals 1, it compares the errors to the best error already found. Value = 0 or 1.
- **CompareEvery:** Error table stride code. The stride is derived from the CompareEvery parameter by the relation  
stride = 1 << CompareEvery.  
The values possible for this parameter are: 0, 1, 2, or 3, indicating a comparison to 1, 2, 4, or 8 errors, respectively.

Table 14-54 shows the iME MCompare4() MSB format.

### 14.3.7.2.8 ClearStatus()

**Function:** Clears the Address field of the best match, the absolute-mean-reached flag, and the iME\_XMVCTm and iME\_YMVCTm tables. Sets the Error field of the best match to 0xFFFF).

**Parameters:** This function does not take any parameter.

Table 14-56 shows the iME ClearStatus() MSB format.

**Table 14-56. iME ClearStatus() MSB Format**

63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32

**14.3.7.2.9 LoadRefBlk()**

**Function:** Loads a reference block (16 × 16 pixels) from L2 memory to be the reference block for computing motion estimates. The L2 address is given through a parameter.

**Parameters:**

- **SL2Address:** Offset in the SL2 space (from the SL2 start address) of the array used to download the reference block from SL2 to iME internal registers. Value = 0 to 0xFFFF. The address of the SL2 array must be 128-bit-aligned.

Table 14-58 shows the iME LoadRefBlk() MSB format.

**Table 14-58. iME LoadRefBlk() MSB Format**

																SL2Address															

**14.3.7.2.10 LoadRefBlk\_Ind()**

**Function:** Loads a reference block (16 × 16 pixels) from L2 memory to be the reference block for computing motion estimates. The L2 address is given through the parameter stack. This instruction is similar to the LoadRefBlk() instruction, but the parameter is passed through the stack instead of being directly hard coded in the OPcode.

**Parameters:**

- **RefBlockAddr:** Index in the parameter stack pointing to the 16-bit offset address from the SL2 start of the array used to download the reference block from SL2 to the iME internal registers. Value = 0 to 0xFFFF. The address of the SL2 array stored in the stack must be 128-bit-aligned.

Table 14-60 shows the iME LoadRefBlk\_Ind() MSB format.

**Table 14-60. iME LoadRefBlk\_Ind() MSB Format**

### 14.3.7.2.11 SaveBestMatch()

**Function:** SaveBestMatch() saves the best match into the stack parameter entry, for which the index is @field0. The error and address fields are swapped in the parameter stack so that the address field is in the LSBs, and can be used for address generation.

**Parameters:**

- **Dst:** Index in the parameter stack to save the best match. Valid destinations are parameter stack entries 16 to 31.

Table 14-62 shows the iME SaveBestMatch() MSB format.

**Table 14-62. iME SaveBestMatch() MSB Format**

63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32

### 14.3.7.2.12 RestoreBestMatch()

**Function:** LoadBestMatch() loads the best match with the stack parameter entry, for which the index is @field0. The error and address fields are swapped in the process, so that the address field is in the MSBs of the best match register.

**Parameters:**

- **Src:** Index in the parameter stack to restore the best match. Valid destinations are parameter stack entries 16 to 31.

Table 14-64 shows the iME RestoreBestMatch() MSB format.

**Table 14-64. iME RestoreBestMatch() MSB Format**

63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32

### 14.3.7.2.13 ExitOnMinReached()

**Function:** ExitOnMinReached() terminates the iME program and sets the iME\_IRQLOG[0] ENDPGMEVENTLOG bit, if the iME\_ABSMINREACHED[0] ABSMINREACHED bit is set.

**Parameters:** This function does not take any parameter.

Table 14-66 shows the iME LoadRefBik() MSB format.

**Table 14-66. iME ExitOnMinReached() MSB Format**

63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32

**14.3.7.2.14 WaitOnSignal()**

**Function:** If the `iME_CONFIGREG[5] SYNC_SIGNAL_SET` bit is reset, `WaitOnSignal()` sets the `iME_CONFIGREG[6] WAITING_FOR_SYNC_SIGNAL` bit. Then, the iME waits until a sync command is sent through the `iME_COMMANDREG` register (`sync()` command is value 0x7). If the `iME_CONFIGREG[5] SYNC_SIGNAL_SET` bit is set, `WaitOnSignal()` resets the `iME_CONFIGREG[5] SYNC_SIGNAL_SET` bit, it does not set the `iME_CONFIGREG[6] WAITING_FOR_SYNC_SIGNAL` bit of the configuration register, and the next instruction executes normally.

**Parameters:** This function does not take any parameter.

Table 14-68 shows the iME LoadRefBlk() MSB format.

**Table 14-68. iME WaitOnSignal() MSB Format**

63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32

**14.3.7.2.15 Memcopy()**

**Function:** Copies up to 256 lines of 256 bits each from shared L2 memory to shared L2 memory. The number of lines is given through a parameter as the source and destination addresses.

**Parameters:**

- **SourceAddress:** Index in the parameter stack pointing to the offset in the SL2 space (from the SL2 start address) of the SL2 array to be copied. Value = 0 to 0x1F.
- **DestAddress:** Index in the parameter stack pointing to the offset in the SL2 space (from the SL2 start address) of the destination SL2 array. Value = 0 to 0x1F.
- **NbElements:** Number of 256-bit lines to be copied  
NbElements varies from 0 to 255.  
If NbElements = 0, 256 lines are copied  
Else NbElements lines are copied

Table 14-70 shows the iME Memcopy() MSB format.

#### 14.3.7.2.16 Interpolate()

**Function:** The interpolate function

**Parameters:**

- **WinStartAddr:** Index in the parameter stack pointing to the offset of the upper-left pixel of the search window in the SL2 space (offset from the SL2 start address)
- **FilterStartAddr:** Index in the parameter stack pointing to the upper-left pixel of the block to interpolate in the search window
- **StoreAddress:** Index in the parameter stack pointing to the upper-left pixel in plane 0 of the interpolated block. It is 128-bit-aligned.
- **LineSize:** Line length, in pixels, of the search window. Value = 8 to 255.
- **IncludeLastBest:** If it equals 0, addressing is based on parameter stack entry. If it equals 1, addressing is based on the best match register. Value = 0 or 1..
- **BlockType:** Size of the block:  
Values:
  - 0x1 for an 8\*8 block
  - 0x2 for a 16\*16 block
  - 0x3 for a 24\*24 block

Table 14-73 shows the iME Interpolate() MSB format.

### 14.3.7.3 Parameters

#### 14.3.7.3.1 Instruction Buffer in L2

Instruction format in L2 is common to iLF and iME. For information about formatting instructions in L2, see [Section 14.3.5.3.1, Instructions](#).

#### 14.3.7.3.2 Generic Parameter Stack in L2

The parameter stack is composed of 16 words of 16 bits and 16 words of 32 bits. When the parameter stack is downloaded from L2 memory to the iME internal registers, a 16-bit mask is applied on the 16 MSB of the first 16 words. The 32 bits of the last 16 words are downloaded in the stack.

The interpolate() instruction use the last 16 words (which are 32-bit words) as interpolate parameters. For more information about interpolate parameters, see [Section 14.3.7.3.3, Interpolate Parameters](#).

SaveBestMatch() and RestoreBestMatch() use one of the last 16 words to store or to restore the best match entry. The word used is defined in the instruction and should be in the last 16 words because the stored value is a 32-bit value.

Data in the generic parameter stack have no order. When required by an instruction, these data are accessed with the help of an index passed as a parameter inside the instruction. This index references the position of the word in the generic parameter stack. The entire parameter stack is addressed through index parameters (0-31).

The generic parameter stack contains three types of parameters:

- Motion vector parameters
- L2 addresses
- Offset

The motion vector parameter stored in the generic parameter stack is 16 bits wide and is composed of 4 fields. [Table 14-75](#) shows the motion vector parameter format.

**Table 14-75. iME Motion Vector Parameter Format**

31:16	15:12	11:8	7:4	3:0
Reserved	Iteration count	Line offset	Lines per iteration	Motion vector type

In the parallel motion vector type, the number of lines used for computation is defined by a variable parameter. Another parameter defines the offset, in number of lines, to read in the reference block. An iteration parameter defines how many times parallel processing is executed (1, 2, or 4 times; new errors are initialized each iteration). The following parameters are used only with the parallel motion vector type. When other motion vector types are used, the field must be filled with 0s:

- Iteration count: Parallel processing iteration (1, 2, or 4)
- Line offset: Line start, from line 0, into the reference block (0, 4, 8, or 12). This field is also used in 4MV and 16 MV.
- Lines per iteration: Number of lines processed per iteration of parallel processing (4, 8, or 16)

The motion vector type parameter determines which motion vector and parameters are used for computation. [Table 14-76](#) shows the different motion vector types with a short description of each and the corresponding encoding in the motion vector type field.

**Table 14-76. iME Motion Vector Type**

MV_type encoding	MV_type name	Description
0x0	1MV_16	16-pixel-wide image
0x1	1MV_8	Downsampled 8-pixel-wide image
0x2	1MV_4	Downsampled 4-pixel-wide image
0x3	Reserved	-
0x4	4MV_L	8-pixel-wide image, left side
0x5	4MV_R	8-pixel-wide image, right side
0x6	Reserved	-
0x7	Reserved	-
0x8	16MV_0	4-pixel-wide image, first quarter
0x9	16MV_1	4-pixel-wide image, second quarter
0xA	16MV_2	4-pixel-wide image, third quarter
0xB	16MV_3	4-pixel-wide image, fourth quarter
0xC	pMV_8	2 // 8-pixel-wide images
0xD	pMV_4	4 // 4-pixel-wide images
0xE	Reserved	-
0xF	Reserved	-

#### 14.3.7.3.3 Interpolate Parameters

When the Interpolate() instruction is used, the interpolation parameters are extracted from the parameter stack. Interpolate parameters are 32-bit-wide words stored in the last 16 words of the parameter stack. For information about how to fill the parameter stack with generic parameters, see [Section 14.3.7.3.2, Generic Parameter Stack in L2](#).

Interpolate instructions also use eight coefficients stored in the IVA.IME\_COEFFREGBANKI registers. These registers must be loaded through the local interconnect, because there is no dedicated instruction to load them from L2 memory. These eight coefficients are stored on 4\*32-bit registers, and their values for the different supported codecs are listed in [Table 14-77](#).

**Table 14-77. iME Interpolate Coefficient Register Bank**

Register Address Offset	MPEG4/H263	H264	WMV9
0x0980	0x00 00 00 00	0x00 FB 00 01	0x00 09 00 FF
0x0984	0x00 00 00 00	0x00 00 00 14	0x00 35 00 FC
0x0988	0x00 00 00 00	0x00 00 00 00	0x00 FD 00 12
0x098C	0x00 00 00 00	0x00 00 00 00	0x00 00 00 24

Values for the interpolate parameter stack for MPEG4, H264, and WMV9 are listed in [Table 14-78](#), [Table 14-79](#), and [Table 14-80](#), respectively. These values are defined by the different video codecs.

H263 and WMV9 use two different sets of parameters, depending on the global rounding frame control parameter (application-dependent). These two sets differ only in their rounding values.

**Table 14-78. iME Interpolate Parameter Stack for MPEG4/H263**

**14.3.7.3.4 Pixel Format in L2**

Pixels are stored in L2 memory before being downloaded to iME internal memory. A set of three parameters is used to indicate which block is compared to the reference block stored in the iME internal memory:

- A search area must be given as a parameter to the ErrorCalc() instruction. This search area is composed of two parameters:
  - Windows store address parameter, referencing the start address of the search area
  - Search area line length parameter, indicating the line length of the search area in L2, which allows the iME to calculate all addresses in the search area
- The current central search position is also passed in parameter. This address references the upper-left pixel of the current block, considered the central block for the current motion estimate. This parameter can be ignored if the UseBestMatchInfo bit is set. When UseBestMatchInfo bit is set, the central search position address corresponds to the address stored in the IVA.IME\_LATESTERRORS BESTMATCHADDRESS field.
- The offset from the central search is given through parameters OffsetH and OffsetV. These values are unsigned, and direction is given with the OffsetCode.

Figure 14-28 describes these parameters.

### 14.3.7.3.5 Motion Vector Cost Table Format in L2

The iME coprocessor includes two MVC tables, `iME_XMVCTm` and `iME_YMVCTm`, each composed of 16 entries of 16 bits. These tables contain cost-correction values used by the MC instruction. Each table is addressed by its two 4-bit indexes, to output one value per parallel comparison. These indexes are generated from an 8-bit OFFSET parameter, the MV type, and the error indexes. [Table 14-81](#) describes how the indexes are calculated. The two selected MVC entries are added together and pipelined to be added to the error value before the comparison.

**Table 14-81. iME Motion Vector Offset Index**

MVType	Error Index	XMVC_index (4 bits)	YMVC_index (4 bits)
pMV4	0	OFFSET & 0xF	OFFSET >> 4
	1	(OFFSET+4) & 0xF	(OFFSET+4) >> 4
	2	(OFFSET+8) & 0xF	(OFFSET+8) >> 4
	3	(OFFSET+12) & 0xF	(OFFSET+12) >> 4
	4	(OFFSET+64) & 0xF	(OFFSET+64) >> 4
	5	(OFFSET+68) & 0xF	(OFFSET+68) >> 4
	6	(OFFSET+72) & 0xF	(OFFSET+72) >> 4
	7	(OFFSET+76) & 0xF	(OFFSET+76) >> 4
	8	(OFFSET+128) & 0xF	(OFFSET+128) >> 4
	9	(OFFSET+132) & 0xF	(OFFSET+132) >> 4
	10	(OFFSET+136) & 0xF	(OFFSET+136) >> 4
	11	(OFFSET+140) & 0xF	(OFFSET+140) >> 4
	12	(OFFSET+192) & 0xF	(OFFSET+192) >> 4
	12	(OFFSET+196) & 0xF	(OFFSET+196) >> 4
	14	(OFFSET+200) & 0xF	(OFFSET+200) >> 4
	15	(OFFSET+204) & 0xF	(OFFSET+204) >> 4
pMV8	i%4=0	OFFSET & 0xF	OFFSET >> 4
	i%4=1	(OFFSET+8) & 0xF	(OFFSET+8) >> 4
	i%4=2	(OFFSET+128) & 0xF	(OFFSET+128) >> 4
	i%4=3	(OFFSET+136) & 0xF	(OFFSET+136) >> 4
Others	i	(OFFSET + i) & 0xF	(OFFSET + i) & 0xF

When the sum of the incoming error and the MV cost correction overflows the 16 bits, the local error is not updated. The comparator behaves as if the incoming data is clipped to the maximum positive integer, which by definition is greater than or equal to the current local error.

The MV cost tables can be loaded from memory with the `loadMVCT()` instruction and then reset by the `clearStatus()` instruction. The 16 entries of each table are packed so that one 256-bit read fills up one complete table.

### 14.3.7.3.6 Error Table

The iME coprocessor includes an error table that stores the result of `ErrorCalc()` to compute the minimum error reached. This table can be accessed through the local interconnect. It is composed of 16 32-bit registers, each composed of 16 bits coding the errors and 16 bits coding the address corresponding to the error. For more information, see [Table 14-651](#), the IVA error table register description. This table is used by the `MCompare()`, `MCompare2()`, and `MCompare4()` instructions as input data. These functions output an error and an address stored in the IVA `iME_LATESTERRORS` register. This register has the same format as the error table registers and can be used as input data during `MCompare()`, `MCompare2()`, and `MCompare4()` instructions, depending on the value of the `IncludeLastBest` parameter.

[Table 14-82](#) shows the error table format.

**Table 14-82. Error Table Format**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ET_ADDRESSN																ET_ERRORN															

The 16 MSBs (bits 16 to 31) denote the offset from the SL2 start address. The 16 LSBs (bits 0 to 15) denote the error field, that is, the absolute SAD value.

### 14.3.8 Video Accelerator/Sequencer Local Interconnect

The video accelerator/sequencer local interconnect allows the DSP megamodule and the sequencer to access the coprocessor, the sequence and video accelerator system control, the shared L2 memory interface, and the IVA2.2 EDMA.

All sequencer reads and writes are performed through the video accelerator/sequencer local interconnect. The DSP can access the interconnect with EFI instructions (EFSDW, EFSW, EFRW, and EFRDW). A write is always composed of an EFSDW (32b). Depending on the destination value associated with the instruction, the pair of DSP megamodule registers contains either the address (32b; only the lowest 20 bits are significant) and the 32b data, or only the 64b data (auto-incrementing, constant addressing mode). A read is composed of a pair of EFSW and EFRW or EFRDW, depending on the size of the read data. For consistency, reads have the same addressing modes as writes.

**NOTE:** The DSP accesses the shared L2 memory and the IVA2.2 EDMA through the IVA interconnect.

Table 14-83 shows the video accelerator/sequencer interconnect memory mapping. Addresses correspond to the DSP megamodule address using the EFI instruction. For sequencer access, all addresses must have an offset, described in Section 14.3.4.8, *Sequencer Memory Mapping*.

For more information about EFI instruction in IVA2.2, see Section 14.4.5, *IVA2.2 Extended Function Interface*.

**Table 14-83. Video Accelerator/Sequencer Memory Mapping**

Device Name	Start Address (Hex)	End Address (Hex)	Size	Description

Reserved	0xF C000	0xF FFFF	16KB	Reserved

### 14.3.9 SL2 Interface

The SL2 memory interface (SL2IF) provides access to L2 memory for the following units:

- iME
- iLF
- Video accelerator/sequencer interconnect

The SL2 memory interface is composed of two modules:

- Bandwidth optimizer (BWO) for video accelerator/sequencer local interface interconnect
- Arbiter

[Figure 14-29](#) is a block diagram of the SL2 memory interface.

Figure 14-29. SL2 Memory Interface Block Diagram

iva22-029

### 14.3.9.1 BWO

The BWO optimizes write bandwidth and read latency for connections from/to the local interconnect from/to the shared L2 memory. It has two components:

- 256b write buffer to gather bursted write data before sending them to the shared L2
- 256b read buffer to prefetch a read line from which the burst is read

These buffers are completely decoupled; writes use the write buffer and reads use the read buffer. This is not a data cache, as there is no load-forwarding from the write buffer, and no prefetch buffer to be updated by an incoming write.

---

**NOTE:** There is no concept of dirty bit and write-back policy.

---

#### 14.3.9.2 Arbiter

The arbiter allows the three modules (iME, iLF, BWO) to access L2 memory without taking care of concurrent access themselves. No bubble is introduced by the arbitration, which means that when a request is initiated by the iME, the iLF, or the BWO, a request is transmitted to the SL2. This arbitration ensures 100 percent bandwidth use. The arbitration is fair and does not starve an initiator for more than three cycles.

To return data to the correct initiator, the arbiter keeps track of the ordering of memory requests committed to the SL2 memory interface.

The SL2 memory interface can sustain a 2x16-byte request per SL2 memory interface clock cycle, whether the request is a read or write or interleaved reads and writes, and regardless of which module generates the request (iME, iLF, or local interconnect port initiators), if the initiator is not preempted by the others (no competition) and provides an equivalent input throughput.

#### 14.3.9.3 Restrictions on SL2 Memory Usage

Because accesses to SL2 (from iME, iLF, or any other initiator with access to the SL2IF interface) are not checked for access permission, the SL2 memory must not be used for memory-protected or sensitive data.

SL2 memory must not be used to store sequencer instructions to be fetched directly by the sequencer; the SL2IF is not designed to efficiently serve sequencer instruction fetches. SL2 memory can hold sequencer instructions, but they must be transferred by the EDMA module into the ITCM before being executed.

#### 14.3.9.4 Error Management

The SL2 memory interface responds to the following conditions with an in-band error (SResp = ERR):

- Nonaligned address (MAddr[1:0] <>0)
- Unsupported command (MCmd not belonging to READ/WR/WRNP)

All valid accesses are propagated to the SL2 memory interface; the address must always be mapped in SL2.

#### 14.3.10 Wake-Up Generator

The wake-up generator (WUGEN) controls the following:

- Implementing the IVA2.2 idle handshake protocol with the PRCM
- Resynchronizing interrupts and DMA requests from device peripherals external to the IVA2.2 subsystem
- Blocking the interrupts and DMA requests to the IVA2.2 on clean boundaries, when the WUGEN is asked to go into IDLE state
- Detecting the enabled wake-up interrupts and DMA requests and generating a wake-up event to the PRCM
- Formatting interrupts to DSP megamodule interrupt format

Figure 14-30 shows the WUGEN in the IVA2.2 subsystem and its interactions with other submodules.

Figure 14-30. IVA2.2 WUGEN Description

iva22-030

### 14.3.10.1 Interrupts, DMA Requests, and Event Management

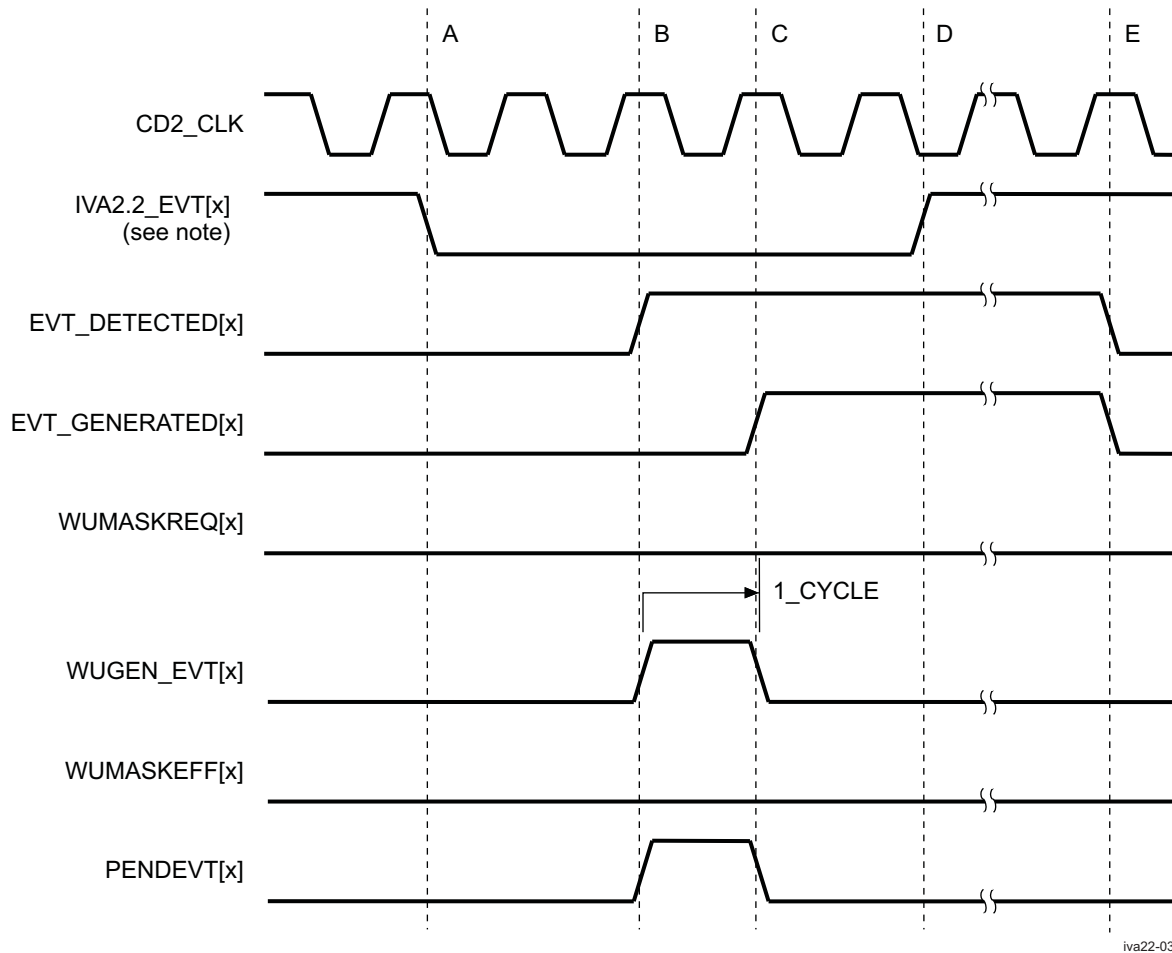

Interrupts and DMA requests are generated the same way in the WUGEN module. In this section, both are called events.

To manage interrupts, DMA requests, and slave port accesses from external modules, the WUGEN module uses several sets of user-programmable registers:

- The [WUGEN\\_MEVT0](#), [WUGEN\\_MEVT1](#), and [WUGEN\\_MEVT2](#) registers define individual mask bits for external asynchronous events (interrupts, DMA requests, slave port access). This register is read-only, only by the DSP. To modify the value of the individual mask, write 1 to the associated bits of [WUGEN\\_MEVTCLR0](#), [WUGEN\\_MEVTCLR1](#), and [WUGEN\\_MEVTCLR2](#) (to clear) and [WUGEN\\_MEVTSET0](#), [WUGEN\\_MEVTSET1](#), and [WUGEN\\_MEVTSET2](#) (to set).
- The [WUGEN\\_PENDEVT0](#), [WUGEN\\_PENDEVT1](#), and [WUGEN\\_PENDEVT2](#) registers are read-only registers that track which external events are pending in the WUGEN module and are not yet generated to the DSP megamodule interrupt controller (INTC) or to the EDMA. If an event is masked, this information is stable until the corresponding mask bit is cleared. If an event is unmasked, this information may not be stable, and therefore corresponds to a transitive period of processing the event in the WUGEN module.

#### 14.3.10.1.1 Event Generation

Figure 14-31 shows event-generation steps in the WUGEN.

**Figure 14-31. WUGEN Event Generation**

**NOTE:** IVA2.2\_EVT[x] refers to either IVA2.2nIRQ[x] or IVA2.2\_nDMAREQ[x].

- (A) An asynchronous event is asserted.
- (B) The event is resynchronized and detected. Because the event is not masked, it is propagated to DSP megamodule/EDMA.
- (C) The event-pending flag is cleared because the event was generated. The event to DSP megamodule/EDMA is deasserted after one WUGEN clock cycle.
- (D) After some time, the source of the event is released (probably because it cleared in the corresponding interrupt status register).
- (E) The release of the event is detected and clears the internal EVT\_GENERATED flag for that interrupt.

#### 14.3.10.1.2 Individual Event Masking

To mask individual events, write 1 in the [WUGEN\\_MEVTSET0](#), [WUGEN\\_MEVTSET1](#), or [WUGEN\\_MEVTSET2](#) register of the WUGEN module. These registers are used to mask interrupts and DMA requests.

Figure 14-32 shows the mechanism of event masking in the WUGEN module.

Figure 14-32. WUGEN Event Masking

iva22-032

**NOTE:** IVA2.2\_EVT[x] refers to either IVA2.2\_nIRQ[x] or IVA2.2\_nDMAREQ[x].

- (A) The user sets the corresponding bit in the mask. Event generation is disabled.
- (B) Event mask completion is reflected in the IVA2.2.WUGEN\_MEVT0 to IVA2.2.WUGEN\_MEVT2 registers (where i = 0 to 2) for reads.
- (C) An asynchronous event is asserted.
- (D) The event is resynchronized and detected. Because the event is masked, it is not propagated to DSP megamodule/EDMA. The event-pending flag is kept active (sticky) until the mask is removed.

#### 14.3.10.1.3 Individual Event Mask Clear

To unmask individual events, write 1 in the WUGEN\_MEVTCLR0, WUGEN\_MEVTCLR1, or WUGEN\_MEVTCLR2 register of the WUGEN module.

Figure 14-33 shows the event-mask-clear mechanism in the WUGEN module.

**Figure 14-33. WUGEN Event Mask Clear**

**NOTE:** IVA2.2\_EVT[x] refers to either IVA2.2\_nIRQ[x] or IVA2.2\_nDMAREQ[x].

- (A) An asynchronous event is asserted.
- (B) The event is resynchronized and detected. Because the event is masked, it is not propagated to DSP megamodule/EDMA. The event-pending flag is kept active (sticky) until the mask is removed.
- (C) After some time, clear the corresponding bit in the WUGEN mask. The event is automatically generated to DSP megamodule if the event is still seen as active. If the event is not seen as active, nothing happens.
- (D) In both cases, the event-pending flag is cleared.

For more information about interrupts and the EDMA programming model, see [Section 14.4.7, Interrupt Management](#), and [Section 14.4.4.1, Transfers From/to Device Memories/Peripherals \(EDMA\)](#).

### 14.3.10.2 Idle Handshake

After reset, the WUGEN waits for a request. If the user executes the DSP IDLE instruction to put the DSP in standby state, the SYSC initiates a clock-off handshake with the WUGEN.

### 14.3.11 SYSC Module

The SYSC module of the IVA2.2 subsystem controls the following functions:

- Generation of the divided clocks to all components of the IVA2.2 subsystem
- Synchronization of the IVA2.2 divided clocks and the DSP megamodule internal-divided clocks
- PRCM power handshaking

- Sequencing of clock-to-off transition for the IVA2.2 modules
- Reset input resynchronization of the active-to-nonactive transition to the CD2\_CLK clock
- IVA2.2 boot configuration and its access from the DSP

Figure 14-34 is the block diagram of the SYSC in the IVA2.2 subsystem.

Figure 14-34. SYSC Block Diagram

iva22-034

**NOTE:** For more information, see [Section 14.2.1, Clocking, Reset, and Power-Management Scheme](#).

### 14.3.11.1 Divided Clock Generation

The SYSC module generates the divided clocks used by the modules in the IVA2.2 subsystem. The SYSC generates three clocks:

- CD0\_CLK
- CD1\_CLK
- CD2\_CLK

Based on the IVA2.2\_FCLK clock, these three clocks are configured from the PRCM. For details, see [Section 14.2.1, Clocking, Reset, and Power-Management Scheme](#).

### 14.3.11.2 Clock Management, Power-Down, and Wake-Up

The SYSC ensures correct generation of the clocks described in [Figure 14-34](#). The SYSC also allows management of the clock gating of the EDMA, video accelerator, sequencer, and DSP megamodule if the user wants to lead some dynamic power aspects.

The SYSC module controls the transition to IVA2.2 subsystem standby state and standby signal generation (IVA2.2\_MSTANDBY signal in [Figure 14-34](#)) to the PRCM. Using the signals DSP\_MEGACELL\_STANDBY, EDMA\_STANDBY, VIDEO\_STANDBY, Mx\_IdleReq, and Mx\_IdleAck, the SYSC manages and controls the correct power-down transition of the IVA2.2 subsystem and its submodules to ensure that the IVA2.2 internal clocks can be cut. For information about the IVA2.2 power-down transition and its programming model, see [Section 14.4.9.3, Power-Down and Wake-Up Management](#).

External events can also occur at the IVA2.2 boundary (access to IVA2.2 using the slave access port or external nonmasked events), requiring the restart of the IVA2.2 clocks (in case of IVA2.2 standby state). The WUGEN module controls the asynchronous generation of a wake-up signal to the PRCM; this signal restarts IVA2.2 PLL clock generation, allowing the SYSC to regenerate the IVA2.2 internal clocks.

### 14.3.11.3 Boot Configuration

The IVA\_SYSC.SYSC\_BOOTADDR and IVA\_SYSC.SYSC\_BOOTMOD registers are the boot-time configuration registers. These read-only registers are accessible only by the DSP, and their values are determined when the IVA2.2 subsystem is released from reset by the PRCM.

The values of these registers are driven externally by two system control module registers, SYSC\_GENERAL1.CONTROL\_IVA2\_BOOTADDR and SYSC\_GENERAL1.CONTROL\_IVA2\_BOOTMOD, which are read-write accessible by the MPU subsystem for MPU-driven IVA2.2 boot sequence and/or by the IVA2.2 DSP for autonomous boot. For more information, see [Section 14.4.1, IVA2.2 Boot](#).

---

**NOTE:** If the values of the SYSC\_GENERAL1.CONTROL\_IVA2\_BOOTADDR and SYSC\_GENERAL1.CONTROL\_IVA2\_BOOTMOD registers change, the new IVA2.2.SYSC\_BOOTADDR and IVA2.2.SYSC\_BOOTMOD register values are not updated until the next reset.

---

For more information, see [Section 14.4.1, IVA2.2 Boot](#).

### 14.3.11.4 Interconnect Optimization

The IVA2.2.SYSC\_LICFG0 and IVA2.2.SYSC\_LICFG1 registers are local interconnect configuration registers. They are read-write accessible by the DSP only. Setting these registers enables or disables interconnect optimization.

### 14.3.11.5 Video Accelerator/Sequencer SYSC

The video and sequencer system control module (called VIDEOSYSC in [Section 14.5.10, Video System Controller Registers](#)) controls module reset, power management, and interrupt handling for the video accelerators/sequencer modules.

#### 14.3.11.5.1 Reset

The reset module resynchronizes asynchronous reset for the following modules:

- iME
- iLF
- SL2IF
- Video and sequencer interconnect
- Sequencer

For details, see [Section 14.2, IVA2.2 Subsystem Integration](#).

#### 14.3.11.5.2 Power Management

The video accelerator/sequencer SYSC controls clock gating for the iLF, iME, and sequencer modules and controls clock division for the sequencer module.

The **VIDEOSYSC\_CLKCTL** register is used to stop or restart the module clocks. A write of 1 requests the module logic to go idle and to stop the clock. A write of 0 requests a restart of logic and clock. When a new request or command occurs, a module automatically exits the IDLE state and the clock starts. Clock gating can be controlled for the following modules:

- SL2 memory interface (controlled by the **VIDEOSYSC\_CLKCTL**[5] SL2IFCLKEN bit)
- Sequencer memory and slave port (controlled by the **VIDEOSYSC\_CLKCTL**[4] SEQMEMCLKEN bit)
- iME module (controlled by the **VIDEOSYSC\_CLKCTL**[1] IMECLKEN bit)
- iLF module (controlled by the **VIDEOSYSC\_CLKCTL**[0] ILFCLKEN bit)

For details, see [Section 14.5.10 Video System Controller Registers](#).

The **VIDEOSYSC\_CLKDIV**[1:0] SEQCLKDIV bit field is used to set a clock divider for the sequencer. A divider of 1, 2, 3, or 4 is available. For details, see [Section 14.5.10, Video System Controller Registers](#).

### 14.3.11.5.3 Interrupt Handler

The video accelerator/sequencer SYSC has a single interrupt output, VIDEO\_INT, which is an active low-level interrupt connected to the DSP megamodule. Once asserted, it can be cleared explicitly only by software. It can be enabled or disabled by software. It is asserted when one of the enabled event lines gets asserted. [Table 14-84](#) lists these interrupts.

**Table 14-84. LSYS Input Interrupts**

Nb	Name	Description
7	Reserved	Reserved
6	SEQ_MBX	Sequencer mailbox IRQ
5	DMA_ERROR	DMA error IRQ
4	HOST_ERROR	HOST error IRQ
3	Reserved	Reserved
2	Reserved	Reserved
1	iLF	iLF IRQ
0	iME	iME IRQ

Four registers are defined for IRQ operation:

- The IVA.**VIDEOSYSC\_IRQSTATE** register tracks input events. Each event is associated with a bit in this register. When the bit is set after an active pulse on the associated event line, this bit is kept active (sticky) until the user explicitly writes 1 to that bit.
- The IVA.**VIDEOSYSC\_IRQMASK** register controls the sensitivity of the interrupt line to input events. Each event is associated with a bit in this register. When the user writes 1 to a bit, the associated active event is not allowed to trigger an interrupt. When the user writes 0, the associated active event triggers an interrupt.
- The IVA.**VIDEOSYSC\_IRQSET** register is used to set the interrupt bits (used to test interrupt). Each event is associated with a bit in this register. When the user writes 1 to a bit, the associated event is set in the IVA.**VIDEOSYSC\_IRQSTATE** register. When the user writes 0, there is no effect.
- The IVA.**VIDEOSYSC\_IRQCLR** register is used to clear the interrupt bits in the IVA.**VIDEOSYSC\_IRQSTATE** register. Each event is associated with a bit in this register. When the user writes 1 to a bit, the associated event is cleared in the IVA.**VIDEOSYSC\_IRQSTATE** register. When the user writes 0, there is no effect.

### 14.3.12 Local Memories

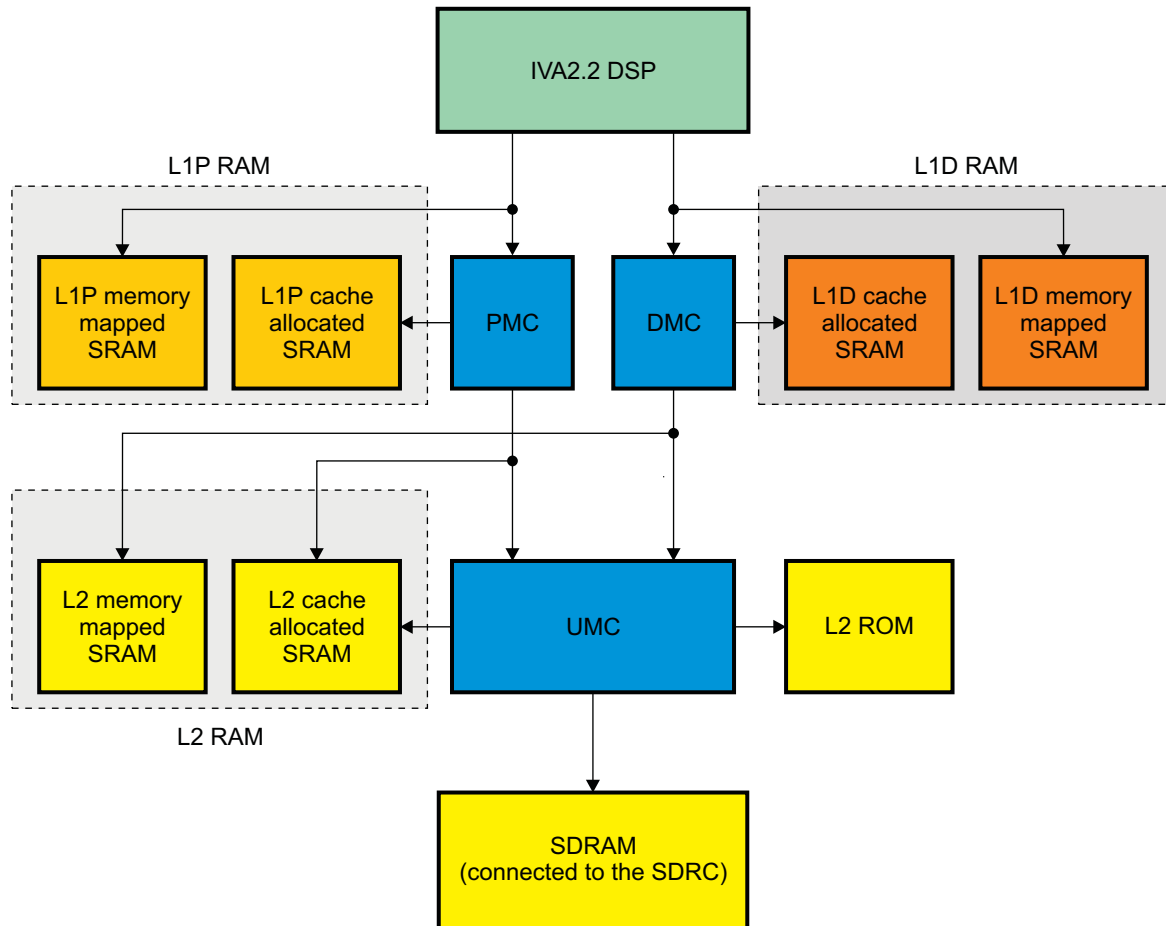

The IVA2.2 subsystem integrates three memory controllers under the control of the DSP megamodule:

- DMC
- PMC
- UMC

Depending on the software configuration of these memory controllers, the IVA2.2 subsystem local memories (ROM and RAMs) can be used as cache or memory-mapped memories.

Figure 14-35 shows the memory hierarchy of the IVA2.2 subsystem.

**Figure 14-35. IVA2.2 Local Memories Hierarchy**

iva22-035

Table 14-85 lists the IVA2.2 DSP megamodule cache controller features.

**Table 14-85. IVA2.2 DSP Megamodule Cache Controller Features**

Cache	L1 Program Cache	L1 Data Cache	L2 Unified Cache
SIZE	Programmable to 0KB, 4KB, 8KB, 16KB, or 32KB	Programmable to 0KB, 4KB, 8KB, 16KB, or 32KB	Programmable to 0KB, 32KB, or 64KB
ASSOCIATIVITY	Direct-mapped	Two-way set associative	Four-way set associative
SRAM MODE [memory-mapped SRAM]	Programmable to 0KB, 16KB, 24KB, 28KB, 32KB [32KB - cache size]	Programmable to 48KB, 64KB, 72KB, 76KB, 80KB [80KB - cache size]	Programmable to 32KB, 64KB, or 96KB [96KB - cache size]
WRITE BUFFER	NR	Yes	Yes
HIT UNDER MISS	Yes	Yes	No
MISS PIPELINING	Yes	Yes	No
REPLACEMENT POLICY	NR	True LRU	True LRU (pseudo-LRU)
CACHEABILITY	Always cached	Programmable	Programmable
BUFFERABILITY	NR	Always buffered	Always buffered
WRITE POLICY	NR	Always write-back	Always write-back
ALLOCATION POLICY	Read-allocate	Read-allocate	Read-write-allocate

**Table 14-85. IVA2.2 DSP Megamodule Cache Controller Features (continued)**

Cache	L1 Program Cache	L1 Data Cache	L2 Unified Cache
CRITICAL WORD FIRST	No	No	No
CRITICAL LINE FIRST	NR	NR	Yes
ADVANCE FETCH	Yes, because of DSP advanced fetch-and-miss pipelining	NR	NR

#### 14.3.12.1 ROM Overview

The IVA2.2 subsystem contains 16KB L2 ROM. The content of this ROM includes boot code.

For information about boot code and the IVA2.2 boot mechanism, see [Section 14.4.1, IVA2.2 Boot](#).

When the L1P SRAM is configured to be inactive (that is, fully memory-mapped SRAM), DSP program fetch accesses to the L2 ROM are realized directly, and thus suffer the L2 latency.

#### 14.3.12.2 RAM Overview

- 32KB L1 program RAM (L1P)
- 80KB L1 data RAM (L1D)
- 96KB L2 unified RAM (L2)

---

**NOTE:** The maximum cache size for the PMC is 32KB. L1P memory-mapped RAM can be programmed to allocate 0KB (full-cache), 16KB, 24KB, 28KB, or 32KB (no cache, default) using the PMC registers. The remaining memory is allocated to the cache controller.

The maximum cache size for the DMC is the default 32K bytes. L1D memory-mapped RAM can be programmed to allocate 48KB (full-cache), 64KB, 72KB, 76KB, or 80KB (no cache, default). The remaining memory is allocated to the cache controller (DMC).

---

L1P and L1D RAM operate at the DSP frequency (CD0 clock domain).

L2 RAM operates at half the DSP frequency (CD1 clock domain).

In the IVA2.2 subsystem, L2 can be configured so that the memory-mapped RAM allocates 32KB, 64KB, or 96KB (no cache) of L2 memory. The remaining memory is allocated to the cache controller

By default, L2 memory is used as 96-KB local memory-mapped RAM. However, L2 RAM is typically used as 64KB allocated to the cache RAM. This is programmable in the DSP megamodule UMC.

The L2 memory-mapped SRAM is shared by the DSP megamodule and the SL2 interface. An arbitration mechanism is implemented for concurrent access, with the DSP megamodule having priority. These last 32KB cannot be used as cache RAM, but only as memory-mapped RAM. Because of address restrictions, the iME and iLF modules can access only the last 32KB of shared L2.

For information about the software programming model for cache management of the local RAM memories of the IVA2.2 subsystem, see [Section 14.4.3, Cache Management](#).

#### 14.3.13 Local Interconnect Network

The local interconnect network is the IVA2.2 internal logic that allows internal communication between the modules of the subsystem (for example, the DSP megamodule can communicate with the EDMA or with the WUGEN module). Communication with the rest of the system is through the MMU as master port (accesses from the IVA2.2 subsystem to the L3 interconnect), and through a slave port for accesses from the L3 interconnect (accesses from the L3 interconnect to the IVA2.2 subsystem).

For information about global memory mapping of the IVA2.2 subsystem (DSP CPU view or MPU view through the L3 interconnect), see [Chapter 2, Memory Mapping](#).

### 14.3.13.1 Endianness

The IVA2.2 local interconnect network does not support the big-endian convention or any type of endianness conversion. Only little-endian is supported by the local interconnect network.

### 14.3.14 Error Reporting

Several mechanisms are available in the IVA2.2 subsystem to report errors at different levels.

The INTC of the DSP megamodule allows reporting of dropped interrupts, through the INTERR signal.

L3 out-of-band errors are also reported through the external L3 interrupt signal. For details about interrupt mapping, see [Table 14-3](#). For information about L3 interconnect error reporting, see [Chapter 5, Interconnect](#).

The IDMA and EDMA have their own error-reporting mechanism. Error-status registers and error interrupts inform the user of problems during IVA2.2 internal operation (data error, bus activity error, etc.).

For information about error management and the register set that allows error tracing, see [Section 14.4.10, Error Identification Process](#).

## 14.4 IVA2.2 Subsystem Basic Programming Model

### 14.4.1 IVA2.2 Boot

The boot-time configuration registers are IVA\_SYSC.SYSC\_BOOTADDR and IVA\_SYSC.SYSC\_BOOTMOD. These read-only registers are accessible only by the DSP CPU, and their values are determined when the IVA2.2 is released from reset, using the CONTROL.CONTROL\_IVA2\_BOOTADDR and CONTROL.CONTROL\_IVA2\_BOOTMOD registers of the system control module. For more information, see [Chapter 7, System Control Module](#). A change to those registers is not seen (not sampled) by the IVA2.2 until the next reset.

The IVA2.2 boots two ways:

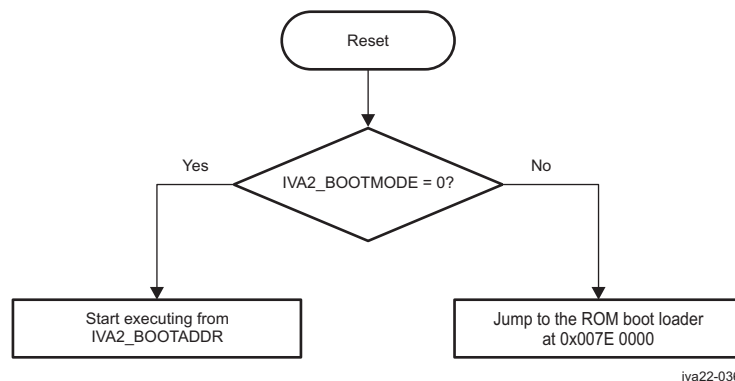

- Boot under MPU control, described in [Section 14.4.1.2.1, Boot Under MPU Control](#).
- Autonomous boot, described in [Section 14.4.1.2.2, Autonomous Boot](#).

A boot under MPU control is typically used after the device cold reset as a first-time configuration of the IVA2.2 subsystem. Subsequent boots of the IVA2.2, resulting from a wake-up transition from OFF state, for example, use the autonomous boot.

#### 14.4.1.1 IVA2.2 Boot Configuration

Figure 14-36 shows the boot sequence followed by IVA2 on release from reset.

Figure 14-36. IVA2 Boot Mode Configuration

When the IVA2.2 subsystem is released from reset and CONTROL.CONTROL\_IVA2\_BOOTMOD[3:0] BootMode equals 0x0, the first fetch address of the C64x equals the address defined in the CONTROL.CONTROL\_IVA2\_BOOTADDR[31:10] BOOTLOADADDR bit field. This address can be aligned on any 1-K byte boundary, in ROM, in IVA2.2 local RAM, in on-chip memory (OCM-RAM), or directly in external memory (for example, SDRAM through the SDRC).

When the IVA2.2 subsystem is released from reset and CONTROL.CONTROL\_IVA2\_BOOTMOD[3:0] BOOTMODE is different from 0x0, the first fetch address of the C64x is fixed to 0x007E0000 (in IVA2.2 local ROM). ROM code boot loader configuration is detailed in [Table 14-86](#).

Table 14-86. Boot Loader Configuration

Value of SYSC_IVA2_BOOTMOD	Description
0x01	IDLE Boot: Boot loader configures the PDCCMD and then executes the IDLE instruction. See <a href="#">Section 14.4.1.1.1</a> .
0x02	Wait in self-loop mode: Boot loader puts IVA2.2 in a self-loop. See <a href="#">Section 14.4.1.1.2</a> .
0x03	Cache Config Mode: Boot loader configures the L1P, L1D, L2 caches and the MAR register. See <a href="#">Section 14.4.1.1.3</a> .
0x04	User defined bootstrap mode: Boot loader copies the boot strap into L2 memory and branches to it. See <a href="#">Section 14.4.1.1.4</a> .
0x05	Reserved.

#### 14.4.1.1.1 IDLE Boot Mode

In this boot mode the **PDCCMD** register is configured before the IDLE instruction is executed. When the IDLE instruction is executed, if there are no pending requests from either the DMA or an interrupt, IVA goes into sleep mode.

The **PDCCMD** register is programmed as shown in [Table 14-87](#).

**Table 14-87. PDCCMD Programmed Value in IDLE Boot Mode**

BitField	Value	Description
GEMPD	1	Sleep mode. Power-down DSP CPU and megamodule when DSP CPU enters IDLE state.
EMCMEM	11	Internal RAMs sleep with retention.
EMCLOG	11	Maximum dynamic clock gating of module regions, with potential : latencies/penalties for wake when megamodule is active and Static clock gating to the EMC when megamodule is in standby.
UMCMEM	11	Sleep mode 3. Internal RAMs sleep with retention, L2 defined at chip-level.
UMCLOG	11	Maximum dynamic clock gating of module regions, with potential latencies/penalties for wake when megamodule is active and Static clock gating to the UMC when megamodule is in standby.
DMCMEM	11	Sleep mode 3. Internal RAMs sleep with retention, L1D defined at chip-level.
DMCLOG	11	Maximum dynamic clock gating of module regions, with potential latencies/penalties for wake when megamodule is active and Static clock gating to the DMC when megamodule is in standby
PMCMEM	11	Sleep mode 3. Internal RAMs sleep with retention, L1P defined at chip-level.
PMCLOG	11	Maximum dynamic clock gating of module regions, with potential latencies/penalties for wake when megamodule is active and Static clock gating to the PMC when megamodule is in standby

#### 14.4.1.1.2 Wait in Self Loop Mode

In this mode boot loader puts the IVA2 in a self-loop. The MPU then has the option to download the bootstrap code from the MPU side directly into IVA2 internal memory through Host Port Interface (L3 slave interface). MPU then sets up **CONTROL.CONTROL\_IVA2\_BOOTMOD[3:0]** BOOTMODE to '0' and **CONTROL.CONTROL\_IVA2\_BOOTADDR[31:10]** BOOTLOADADDR to the internal memory address where it copied the bootstrap, IVA2.2 is then released from reset. Upon completion of the reset sequence IVA2.2 jumps to the bootstrap code loaded by the user in its internal memory and starts executing it.

#### 14.4.1.1.3 Default Config Cache Mode

In this mode the boot loader configures the L1P, L1D, L2 caches and the MAR registers of DSP megamodule. After performing this configuration the boot loader branches to an external memory address. The values with which these settings are done and the external memory address to which the boot loader jumps is specified using a header.

[Table 14-88](#) specifies the format of the header.

**Table 14-88. Header Format Used in Default Config Cache Mode**

Offset from Base Address of Header (in bytes)	Fields Description
0x00	Value of <b>L1PCFG</b> register to be loaded.
0x04	Value of <b>L1DCFG</b> register to be loaded.
0x08	Value of <b>L2CFG</b> register to be loaded.
0x0C	1 -> Set PC bit of all <b>MAR<sub>i</sub></b> registers to 1 0 -> No action will be taken as by default PC bit of all <b>MAR<sub>i</sub></b> registers is set to 0
0x10	Address of external memory to which boot loader should branch to.

The address of this table (header) should be specified in the CONTROL.CONTROL\_IVA2\_BOOTADDR[31:10] BOOTLOADADDR register before IVA2.2 is released from reset.

Setting of the L1PCFG, L1DCFG, and L2CFG is done as follows:

- The desired cache mode is written to the L1PCFG, L1DCFG, and L2CFG.
- L1PCFG, L1DCFG, and L2CFG are read back. This stalls the CPU until the mode change completes

Setting of the MAR registers is done as follows:

- The desired value (in our case 1) is written to the MAR
- The final value written to the MAR address is read back. This stalls the CPU until all the MAR writes are completed.

#### 14.4.1.1.4 User Defined Bootstrap Mode

In this mode the boot loader downloads a user bootstrap code, which is kept in the external memory, into the L2 memory of IVA2.2. After transferring, the boot loader branches to the user bootstrap code. Please note that all sections of the user bootstrap code should fit into L2 memory and no section of the bootstrap code should be mapped to either L1P or L1D memory.

Various parameters that the boot loader needs to transfer the bootstrap code are provided using a user bootstrap header present in the external memory. The CONTROL.CONTROL\_IVA2\_BOOTADDR[31:10] BOOTLOADADDR is setup with the address of this user bootstrap header before IVA2.2 is released from reset.

Table 14-89 specifies the format of the bootstrap header.

**Table 14-89. Header Format Used in User Defined Bootstrap Mode**

Offset from Base Address of Header (in bytes)	Fields Description
0x00	Size of the boot strap code in bytes that will be downloaded into internal memory.
0x04	0 -> Use DMA for transferring the bootstrap code 1 -> Use CPU copy for transferring the bootstrap code.
0x08	Value of L2CFG register to be loaded.
0x0C	Absolute address of L2 memory where the boot strap code is to be copied.
0x10	Offset in bytes from the beginning of the bootstrap code where the first executable instruction of the bootstrap is present.
0x14	Absolute address in external memory from where the bootstrap code will be copied.

---

**NOTE:** It is mandatory for the user bootstrap code to be a multiple of 4 words on IVA2.2

---

#### 14.4.1.2 Example of IVA2.2 Boot

##### 14.4.1.2.1 Boot Under MPU Control

Before waking up the IVA2.2 subsystem, the MPU performs the following sequence (also shown in Figure 14-37):

1. The MPU prepares a translation table hierarchy (TTH) in SDRAM at address <TTH Physical Address>. This TTH must contain at least an address translation for the IVA2.2 MMU physical address range.

---

**NOTE:** The DSP CPU does not require an address translation for the TTH, as the TTH is under MPU control only. The IVA2.2 DSP CPU is responsible only for saving and restoring an IVA2.2 MMU context that has been programmed by the MPU.

---

2. The MPU writes a bootstrap sequence in SDRAM at address <BootLoader Physical Address>. This

sequence is executable by the DSP CPU and contains only relative address references, so that it is relocatable without code modification. This sequence must contain at least (in order):

- (a) Set the size of the bootstrap code.
- (b) Program the IVA2.2 MMU using physical addresses, as described in the following steps.

---

**NOTE:** The device has two instances of MMU: camera MMU or MMU1 (used for the camera subsystem) and IVA2.2 MMU or MMU2 (used for the IVA2.2 subsystem). These two instances are programmed by two identical sets of configuration registers. For more information, see [Chapter 8, Memory Management Units](#).

---

3. Programming of the MMU2 is functionally restricted to setting the MMU2.MMU\_CNTL[1] MMUENABLE bit, and the TLB misses are served by the MPU-dedicated interrupt service routine (ISR). However, MMU table-walking logic is preferred because the IVA2.2 must be autonomous after the preliminary settings.

Moreover, it is critical that the duration of the MMU save-and-restore process use a minimum number of cycles, so that address translation for the MMU configuration registers uses a TLB locked entry. For those reasons, it is recommended that the bootstrap follow the MMU initialization sequence:

- (a) Write <TTH physical address>[31:7] to the MMU2.MMU\_TTB[31:17] TTBADDRESS bit field.
- (b) Lock the address translation for the MMU configuration registers.
  - (i) Write 0x0 to the MMU2.MMU\_LOCK[8:4] CURRENTVICTIM bit field.
  - (ii) Write <MMU virtual address>[31:12] to the MMU2.MMU\_CAM[31:12] VATAG bit field.
  - (iii) Write 1 to the MMU2.MMU\_CAM[2] V bit.
  - (iv) Write 0x2 to the MMU2.MMU\_CAM[1:0] PAGESIZE bit field.
  - (v) Write <MMU physical address>[31:12] to the MMU2.MMU\_RAM[31:12] PHYSICALADDRESS bit field.
  - (vi) Write 1 to the MMU2.MMU\_LD\_TLB[0] LDTLBITEM bit.
  - (vii) Write 0x1 to the MMU2.MMU\_LOCK[8:4] CURRENTVICTIM bit field.
  - (viii) Write 0x1 to the MMU2.MMU\_LOCK[14:10] BASEVALUE bit field.
- (c) Write 1 to the MMU2.MMU\_CNTL[2] TWLENABLE bit.
- (d) Write 1 to the MMU2.MMU\_CNTL[1] MMUENABLE bit.
- (e) Read back the MMU2.MMU\_CNTL register to ensure write completion.

---

**NOTE:** This read does not generate a TLB miss, because the address translation for MMU configuration registers is locked in the TLB.

---

4. The MPU can lock some other TLB entries, define some power-management MMU settings, and/or enable some interrupts.
5. The MPU correctly programs the associated L3 firewall, ensuring that the DSP CPU has read access to the memory area containing the IVA2.2 bootstrap sequence.
6. The MPU programs the associated L3 firewall, ensuring that the DSP CPU has read and write access to the configuration registers of the MMU2.
7. The MPU writes <bootloader physical address> to the CONTROL.CONTROL\_IVA2\_BOOTADDR[31:10] BOOTADDR bit field and configures the correct CONTROL.CONTROL\_IVA2\_BOOTMOD[3:0] BOOTMOD bit field nonzero value.

---

**NOTE:** For a detailed description of the system boot registers, see [Chapter 7, System Control Module](#).

---

8. The MPU configures the IVA2.2 clock rate and IVA2.2-related power-management settings in the PRCM.

After initialization completes, the MPU allows the IVA2.2 to boot:

- (a) The MPU releases the IVA2.2 from the OFF state by programming the PRCM.

- (b) The MPU sets the clocks back to the IVA2.2.
- (c) The MPU releases the IVA2.2 from reset.

**NOTE:** Following Steps 1 through 8, the IVA2.2 boot sequence is identical to the autonomous boot sequence. For information about the IVA2.2 boot sequence, see [Section 14.4.1, IVA2.2 Boot](#).

**Figure 14-37. IVA2 Boot Basic Programming Model**

iva22-037

#### 14.4.1.2.2 Autonomous Boot

On an OFF-to-ACTIVE transition (under MPU control or upon interrupt wakeup), the IVA2.2 subsystem is released from reset.

After hardware configuration of values for DSP megamodule generic parameters, the IVA2.2 starts fetching from the address 0x00000000 in ROM. The IVA2.2 must follow the (nonexhaustive) boot process:

1. Configure memory protection:
  - (a) Specify cache RAMs versus IDMA and DMA accesses.
  - (b) Define accessible L2 space (static shared L2 with the MPU/LCD).
2. Load the bootstrap code:
  - (a) Read the IVA\_SYSC.SYSC\_BOOTADDR[31:12] BOOTLOADADDR bit field.
  - (b) Read the number of bootstrap words <NbOfWords> to transfer in the first word at the address pointed to by BOOTLOADADDR.
  - (c) Transfer as many words as defined in <NbOfWords>.
3. Execute the bootstrap code.

**NOTE:** This prepares the MMU for address translation of external accesses. In the case of a boot upon interrupt wakeup, the MMU is restored to its exact context before the IVA2.2 is shut off, if this context was saved correctly.

Only from this point can the IVA2.2 subsystem work with virtual addresses.

### 14.4.2 Sequencer Boot/Reset

After the reset input signal is applied to the video accelerator/sequencer, all modules are operational except the sequencer CPU, which is maintained under reset so that the host can initialize some configuration registers and upload some boot code in the ITCM and DTCM memories of the sequencer.

The sequencer reset is connected on IVA2\_RST3, and this reset is controlled by the PRCM. The DSP megamodule or the MPU can release the IVA2\_RST3 by clearing the PRCM.RM\_RSTCTRL\_IVA2[2] RST3\_IVA2 bit.

When the sequencer reset (IVA2\_RST3) is released, the sequencer starts fetching instructions from ITCM memory, which is initialized by the DSP megamodule or the MPU before the sequencer reset is released. Thus, a classic boot/reset sequence follows the sequence (only the sequencer is under reset; other modules like iME and iLF are already out of reset):

1. The DSP initializes the ITCM sequencer memory with sequencer code.
2. The DSP initializes the DTCM sequencer memory with sequencer data.
3. The DSP sets the clock divider for the sequencer module in the IVA.VIDEOSYSC\_CLKDIV register.
4. The DSP releases the sequencer from reset by clearing the PRCM.RM\_RSTCTRL\_IVA2[2] RST3\_IVA2 bit.

The sequencer is autonomous (no longer under DSP control).

The DSP and the sequencer processor communicate through a message box; two interrupts are provided for this purpose.

---

**NOTE:** For more information about sequencer boot/reset, see *ARM968E-S Technical Reference Manual ARM*.

---

### 14.4.3 Cache Management

The IVA2.2 subsystem has a 2-level cache-based architecture. Level 1 data memory/cache (L1D) consists of an 80-KB memory space dedicated to data. L1D memory can be configured as mapped memory, cache, or a combination of the two. The level 1 program memory/cache (L1P) consists of a 32-KB memory space dedicated to program instructions. L1P memory can be configured as mapped memory, cache, or a combination of the two. Level 2 memory/cache (L2) consists of a 96-KB memory space shared by program and data space. L2 memory can be configured as mapped memory, cache, or a combination of the two.

Configuration of the allocation of the L1D, L1P, and L2 memories to mapped memory and/or cache is described in [Section 14.4.3.1, Cache-Size Configuration](#).

The virtual address space is split into contiguous chunks to configure which parts of the memory are cacheable and not cacheable. Configuration of cacheability is described in [Section 14.4.3.3, Cacheability Settings](#).

#### 14.4.3.1 Cache-Size Configuration

Cache-size configuration is controlled by a set of registers: IVA\_XMC.L1PCFG, IVA\_XMC.L1DCFG, and IVA\_XMC.L2CFG, that correspond to the L1P, L1D, and L2 memories, respectively.

The IVA\_XMC.L1PCFG register allows the selection of the size of the L1P cache. The user selects the size of the L1P cache by writing the requested mode to the L1PCFG[2:0] L1PMODE bit field.

[Table 14-90](#) lists the valid settings of L1PMODE.

**Table 14-90. Cache Size Specified by L1PMODE**

L1PCFG[2:0] L1PMODE	Amount of L1P
Setting	Cache
000b	0 KB (default)
001b	4KB

**Table 14-90. Cache Size Specified by L1PMODE (continued)**

<b>L1PCFG[2:0] L1PMODE</b>	<b>Amount of L1P</b>
010b	8KB
011b	16KB
100b	32KB
101b	Not used
110b	Not used
111b	Maximum cache (maps to 32KB)

The IVA\_XMC.L1DCFG register allows the selection of the size of the L1D cache. The user selects the size of the L1D cache by writing the requested mode to the L1DCFG[2:0] L1DMODE bit field.

Table 14-91 lists the valid settings of L1DMODE.

**Table 14-91. Cache Size Specified by L1DMODE**

<b>L1DCFG[2:0] L1DMODE</b>	<b>Amount of L1D</b>
Setting	Cache
000b	0KB (default)
001b	4KB
010b	8KB
011b	16KB
100b	32KB
101b	Not used
110b	Not used
111b	Maximum cache (maps to 32KB)

In the same way, the L2CFG[2:0] L2MODE bit field controls the size of the L2 cache. The user sets the amount of L2 memory mapped as L2 cache by writing the desired cache mode to this bit field.

Table 14-92 shows the valid settings for L2MODE.

**Table 14-92. Cache Size Specified by L2MODE**

<b>L2CFG[2:0] L2MODE</b>	<b>Amount of L2</b>
Setting	Cache
000b	0KB (default)
001b	32KB
010b	64KB

When programs initiate a cache mode change, the L1D cache must write back and invalidate its current contents without losing data. This ensures that all updated data held in cache is written back, and that no false hits occur because of a change in the interpretation of cache tags. It also ensures that the L1D snoop tag RAM in the UMC stays in sync with L1D.

While the write-back-invalidate is required to ensure correct cache behavior and to ensure that no cached data is lost, it is not sufficient to prevent data loss as a result of portions of L1D RAM becoming cache. To safely change L1D cache modes, applications must adhere to the procedure described in Table 14-93.

**Table 14-93. Switching Cache Modes**

<b>To switch from</b>	<b>To</b>	<b>The program must perform the following steps:</b>
A mode with no or some cache	A mode with more cache	1: EDMA, IDMA, or copy necessary data out of the affected range of RAM.  2: Write the desired cache mode to the bit field in the configuration cache register (L1DCFG, L1PCFG, and L2CFG).

**Table 14-93. Switching Cache Modes (continued)**

To switch from	To	The program must perform the following steps:
A mode with some cache	A mode with less or no cache	3: Read back the register to stall the DSP CPU until the mode change completes. 1: Write the desired cache mode to the bit field in the cache configuration register concerned. 2: Read back the register to stall the DSP CPU until the mode change completes.

L1P RAM is typically used as cache RAM, with no local flat RAM (not the default; must be configured by the user).

L1D RAM is typically used as 32KB allocated to the cache RAM and 48KB has local memory-mapped RAM. By default, L2 memory is configured as 0KB allocated to the cache RAM and 96KB as local memory-mapped RAM (see [Table 14-94](#)).

**Table 14-94. Default Cache Configuration**

Memory Type	Memory Size	Default Cache Setting
L1P RAM	32KB	0KB cache
L1D RAM	80KB	0KB cache
L2 RAM	96KB	0KB cache

#### 14.4.3.2 Cache Mode Configuration

The memory cache controllers of the DSP megamodule (L1D, L1P, and L2) offer two additional operating modes: freeze and/or bypass. These modes are set by the [L1DCC\[2:0\] OPER](#) bit field for L1D, the [L1PCC\[2:0\] OPER](#) bit field for L1P, and the [L2CFG\[4:3\] L2CC](#) bit field for L2.

The freeze and bypass modes affect the operation of only the cache section (no impact on the memory-mapped section of the memory) of each memory controller.

This feature allows real-time applications to limit the amount of data evicted from cache controllers, such as interrupt handlers, during various sections of code.

[Table 14-95](#) summarizes the freeze and bypass modes for each cache controller (set through the OPER field in the [L1PCC](#) register for the L1P cache controller, the OPER field in the [L1DCC](#) register, and the L2CC field of the [L2CFG](#) register for the L2 cache controller).

**Table 14-95. Cache Mode Configuration**

Cache Controller	Operation Mode		
	Normal	Freeze	Bypass
L1P	Cache operates normally. Read hits return data from the cache. Write hits update the cached data for the cache line.	The L1P cache does not allocate new cache lines on read misses, nor does it cause existing cache contents to be marked invalid. Write misses are dropped.  The L1P cache responds normally to program-initiated cache controls (invalidate, mode change).	N/A
L1D	Cache operates normally.	The L1D cache does not allocate new cache lines on read misses, nor does it evict existing cache contents.  The L1D cache responds normally to program-initiated cache commands (invalidate, write-back-invalidate mode change).	N/A

**Table 14-95. Cache Mode Configuration (continued)**

Cache Controller	Operation Mode		
	Normal	Freeze	Bypass
L2	Cache operates normally.	Cache frozen. Hits proceed normally. L2 sends read and write misses directly to external memory, as if the L2 cache is not present. The L2 does not allocate a new cache line while frozen. Lines can be evicted from L2 only during freeze mode by program-initiated cache coherence operations.	Cache disabled, although internal cache state is retained. When in bypass mode, the L2 cache responds to neither reads nor writes. All requests for external addresses are sent externally. L2 does not update its contents in this mode. As with freeze mode, L2 evicts lines from L2 only during bypass mode as a result of program-initiated cache coherence operations.

### 14.4.3.3 Cacheability Settings

The address space of the IVA2.2 subsystem is split into contiguous regions of 16M bytes each. Each region has a cacheable attribute that defines whether a reference to a location belonging to the associated memory region must be sent directly to the memory (with exact size and occurrence as requested by the CPU) or must induce a cache line refill and potentially an eviction of another cache line.

The UMC contains registers that control whether certain ranges of memory are cacheable, and whether one or more requestors is allowed access to these ranges.

### 14.4.3.4 Coherence Maintenance

#### 14.4.3.4.1 Memory-Mapped L1P and L1D Coherence

L1D and L1P are never cached, so there is no coherence maintenance for those memories.

#### 14.4.3.4.2 Memory-Mapped L2 Coherence

Coherence is maintained by hardware between L1D cache content and the L2 memory-mapped memory region.

An L2 reference from the DSP CPU updating an L1D cache location is automatically made visible to the DMA and any master processor on the device with access to the DSP megamodule memory-mapped L2 through the IVA2.2 slave port.

An L2 reference from the DMA and any other master processor on the device with access to the DSP megamodule memory-mapped L2 through the IVA2.2 subsystem slave port is automatically made visible to the DSP CPU through the L1D cache, if it is holding the associated cache line.

---

**NOTE:** To reduce the complexity of the L1P cache controller to the L2 controller interface, the L1P cache coherency protocol is removed. This means that coherency between L2 cache and L1P cache is not maintained. On the C64x+ CPU, writes to L2 do not invalidate the corresponding region in L1P. This must be done manually.

---

#### 14.4.3.4.3 Device Memory Coherence

Coherence is not maintained by hardware between the L2 cache (and L1D cache/L1P cache) and device memories (on-chip memories external to the IVA2.2 subsystem and off-chip memories connected to the SDRAM controller and/or general-purpose memory controller [GPMC]). Coherence in this case must be handled by software. The DSP megamodule offers two sets of registers for user-initiated coherence maintenance between DSP local memories and device memories.

Software coherence maintenance must be synchronized in the system (for example, through message passing; for information, see [Chapter 6, Interprocessor Communication](#)). In the producer/consumer model, the producer sends a completion message to the consumer only after the write is complete in end memory. If the producer has a cache-based architecture, the producer must initiate a write-back and track for the completion of the write-back sequence in end memory. For a description of how the write-back sequence occurs in the IVA2.2 subsystem, see [Section 14.4.3.4.6, Write-Back Completion](#). When the consumer receives the message, if the consumer has a cache-based architecture, updates by the producer must be effectively seen (not a local nonupdated copy). For a description of how the invalidate sequence occurs in the IVA2.2 subsystem, see [Section 14.4.3.4.4, Global Cache Management](#).

Two types of cache coherence management are possible:

- Global cache coherence allows the DSP CPU to ensure coherence of the entire cache at once. See [Section 14.4.3.4.4, Global Cache Management](#).
- Block cache coherence allows the DSP CPU to ensure coherence of a contiguous region of the virtual address map, restricted in size to only what is needed. See [Section 14.4.3.4.5, Block Cache Management](#).

Each management type provides three sets of actions:

- Invalidate ensures that all required lines are made invalid in the cache. After that operation, any update (before invalidate operation) in end memory by an alternate processor/DMA is seen by the DSP CPU, forcing a cache line refill.
- Write-back ensures that all required cache lines modified by the DSP CPU (also called dirty lines) are written back to end memory, so that any local update by the DSP CPU is made visible by an alternate processor/DMA. This applies only to L1D cache and L2 cache, not to L1P cache.
- Write-back and invalidate ensure that all required cache lines modified by the DSP CPU (also called dirty lines) are written back to end memory so that any local update by the DSP CPU is made visible by an alternate processor/DMA, and they ensure that all required lines are made invalid in the cache. After that operation, any update in end memory by an alternate processor/DMA is seen by the DSP CPU, forcing a cache line refill. This applies only to L1D cache and L2 cache, not to L1P cache.

#### 14.4.3.4.4 Global Cache Management

This section describes how to invalidate and write back the cache memory

- Global invalidate

Global invalidate is controlled by the following registers: IVA\_XMC.L2INV, IVA\_XMC.L1DINV, and IVA\_XMC.L1PINV.

Example of global invalidate:

```

/* ----- */
/* Invalidate anything held in cache. */
/* ----- */
L2INV = 1;
/* ----- */
/* Now, spin waiting for operation to complete. */
/* ----- */
while ((L2INV & 1) != 0)
;

```

L2INV = 0 ensures that L1D cache and L1P cache are also globally invalidated before the L2 cache invalidate process.

- Global write-back

Global write-back is controlled by the following registers: IVA\_XMC.L2WB and IVA\_XMC.L1DWB.

Example of global write-back:

```

/* ----- */
/* Write back anything held in cache. */
/* ----- */

```

```

L2WB = 1;
/* ----- */
/* Now, spin waiting for operation to complete. */
/* ----- */
while ((L2WB & 1) != 0)
;

```

To ensure write-back completion of a specific buffer (contiguous address range), see [Section 14.4.3.4.6, Write-Back Completion](#), for additional programming steps and an example.

- Global write-back and block invalidate

Global write-back and block invalidate is controlled by the following registers: IVA\_XMC.L2WBINV and IVA\_XMC.L1DWBINV.

Example of global write-back and block invalidate:

```

/* ----- */
/* Write back and invalidate anything held in cache. */
/* ----- */
L2WBINV = 1;
/* ----- */
/* Now, spin waiting for operation to complete. */
/* ----- */
while ((L2WBINV & 1) != 0)
;

```

To ensure write-back completion of a specific buffer (contiguous address range), see [Section 14.4.3.4.6, Write-Back Completion](#), for additional programming steps and an example.

#### 14.4.3.4.5 Block Cache Management

- Block invalidate

Block invalidate is controlled by the following registers: IVA\_XMC.L2BAR, IVA\_XMC.L2IWC, IVA\_XMC.L1DIBAR, IVA\_XMC.L1DIWC, IVA\_XMC.L1PIBAR, and IVA\_XMC.L1PIWC.

Example of block invalidate:

```

/* ----- */
/* Write base address of array to Base Address Register. /
/* Then write length of the array, in words, to the Word*/
/* Count register. */
/* ----- */
L2IBAR = &array[0];
L2IWC = = sizeof(array) / sizeof(int);
/* . . . */
/* ----- */
/* The CPU can execute other code here. Block cache operations proceed in parallel with CPU
execution, stalling the CPU minimally. */
/* ----- */
/* . . . */
/* ----- */
/* Now, spin waiting for operation to complete. */
/* ----- */
while (L2IWC != 0)
;

```

[L2IWC](#) = 0 ensures that L1D cache and L1P cache are also block invalidated before the L2 cache invalidate process.

- Block write-back

Block write-back is controlled by the following registers: IVA\_XMC.L2WBAR, IVA\_XMC.L2WWC, IVA\_XMC.L1DWBAR, and IVA\_XMC.L1DWWC.

Example of block write-back:

```

/* ----- */
/* Write base address of array to Base Address Register.*/
/* Then write length of array, in words, to the Word */
/* Count register. */
/* ----- */
L2WBAR = &array[0];
L2WWC = sizeof(array) / sizeof(int);
/* . . . */
/* ----- */
/* CPU can execute other code here. Block cache operations proceed in parallel with CPU
execution, stalling CPU minimally. */
/* ----- */
/* . . . */
/* ----- */
/* Now, spin waiting for operation to complete. */
/* ----- */
while (L2WWC != 0)
;

```

To ensure write-back completion of a specific buffer (contiguous address range), see [Section 14.4.3.4.6, Write-Back Completion](#), for additional programming steps and an example.

- Block write-back and invalidate

Block write-back and invalidate is controlled by the following registers: IVA\_XMC.L2WIBAR, IVA\_XMC.L2WIWC, IVA\_XMC.L1DWIBAR, and IVA\_XMC.L1DWIWC.

Example of block write-back and invalidate:

```

/* ----- */
/* Write base address of array to Base Address Register.*/
/* Then write length of array, in words, to the Word */
/* Count register. */
/* ----- */
L2WIBAR = &array[0];
L2WIWC = (array) / sizeof(int);
/* . . . */
/* ----- */
/*The CPU can execute other code here. Block cache operations proceed in parallel with CPU
execution, stalling the CPU minimally. */
/* ----- */
/* . . . */
/* ----- */
/* Now, spin waiting for operation to complete. */
/* ----- */
while (L2WIWC != 0)
;

```

To ensure write-back completion of a specific buffer (contiguous address range), see [Section 14.4.3.4.6](#) for additional programming steps and an example.

#### 14.4.3.4.6 Write-Back Completion

The `SYSC_LICFG0[15]` `GEMTRUECOMPEN` bit must be set to 1 before any DSP CPU C64x+ write for which completion must be ensured. This applies to writes to noncacheable regions and to cache-line write-back completions. By default, `SYSC_LICFG0[15]` `GEMTRUECOMPEN` = 0. This default is recommended, to statically set that bit (unless the user wants to locally send a large number of writes to a noncacheable memory region):

- `SYSC_LICFG0.GEMTRUECOMPEN` = 1;

Polling on the `L*WWC` (resp. `L*WIWC`) ensures that the block write-back operation (and associated invalidate, when applicable) was completely issued by the associated cache controller, but does not ensure that the write-back is effective in end memory.

To get completion of the write-back of a specific buffer after block or global cache write-back, the user must read back from a noncacheable region of the same L3 or L4 target as the buffer (if data is written in external DDR memory, the read access can be on an SDRG register). The C64x+ is unstalled only after the read following the write-back is complete.

In the producer/consumer model, the cache-based producer typically ensures that the produced buffer is visible to the consumer of that buffer by writing back the address range of that buffer and checking for completion of the write-back sequence before sending a completion message to the consumer.

Example:

```

/* ----- */
/* nonCachedArea to be linked to non-cached SDRAM region*/
/* ----- */
#pragma DATA_SECTION(nonCachedDummyVar, ".nonCachedArea")
volatile int nonCachedDummyVar;
/* ----- */
/* outBuffer is produced buffer in SDRAM to be visible to the consumer */
/* ----- */
L2WBAR = &outBuffer[0];
L2WWC = sizeof(outBuffer) / sizeof(int);
/* ----- */
/* L2WWC ensures the sequence is completed by the cache controller but not completed in end
memory */
/* ----- */
while (L2WWC != 0)
;
/* ----- */
/*C64x+ is stalled until dummy memory read has completed which the hardware ensures happens after
write-back of outBuffer completed in SDRAM. */
/* ----- */
int dummyRead = nonCachedDummyVar;
/* ----- */
/* Then C64x SW (producer) can send message to consumer */
/* ----- */

```

- `sendCompletionMsgToConsumer()`;

---

**NOTE:** To ensure completion, the `nonCachedDummyVar` must be in the same target as the written-back buffer.

---

In the case of the C64x writing in the noncache area: To ensure the completion of the C64x write in physical end memory, set the `SYSC_LICFG0 [15]` `GEMTRUECOMPEN` bit to 1 and also read back after the last C64x write.

1. DSP write and DMA read

The user writes to some noncache region with DSP and then reads from the same area with DMA.

To ensure completion of the DSP write in physical end memory, set the SYSC.LICFG0[15] GEMTRUECOMPEN bit to 1 and also read back after the last DSP write. The sequence is:

- (a) Set the SYSC\_LICFG0[15] GEMTRUECOMPEN bit to 1.
- (b) DSP writes data in external memory, noncache area.
- (c) DSP reads data in external memory, noncache area: last write data for instance.
- (d) DMA reads data from external memory.

#### 2. DMA write and DSP read

The opposite of 1. To ensure the completion of DMA write in physical end memory, set the SYSC\_LICFG0 DMATRUECOMPEN bit to 1 and PARAM [LCHi].OPT.TCCMODE to 0 (no early completion). The sequence is:

- (a) Set the SYSC\_LICFG0.DMATRUECOMPEN bit to 1.
- (b) Set PARAM[LCHi].OPT.TCCMODE to 0.
- (c) Set PARAM[LCHi].OPT.TCCMODE to 0.
- (d) DSP waits for end of DMA transferred:
  - IPR/IPRH bit update (for polling-scheme)
  - Interrupt generation (for interrupt-scheme)
  - CER/CERH bit update (for chaining)
  - DSP reads data from external memory.

#### 14.4.3.4.7 Performance Consideration Timing

Long burst is key to improving the efficiency of the SDRAM and reducing cache-line refill and cache-line write-back latencies. The IVA2.2 subsystem allows for improving the burst generation over the device interconnect. This is configurable with the SYSC\_LICFG0[16].GEMBURSTOPTEN bit. By default, SYSC\_LICFG0[16] GEMBURSTOPTEN = 0, and the burst optimization is disabled. This default is recommended to statically set the bit:

SYSC\_LICFG0.GEMBURSTOPTEN = 1

### 14.4.4 DMA Management

#### 14.4.4.1 Transfers From/to Device Memories/Peripherals (EDMA)

The EDMA optimizes transfers from/to the DSP megamodule (memory-mapped) memories to/from device on-chip and off-chip memories.

The EDMA can perform transfers from IVA2.2 internal memories to IVA2.2 internal memories, but it is not designed for that purpose. The IDMA is recommended in that case (unless a 2-dimensional transfer is required).

The EDMA can perform transfers from device memories/peripherals to device memories/peripherals, but it is not designed for that purpose. The sDMA is recommended in that case. For more information, see [Chapter 9, DMA](#).

#### 14.4.4.2 Internal Memory-to-Memory Transfer (IDMA)

The user can quickly page memory regions or fill a memory region of the DSP megamodule memories by using channel 1 of the IDMA module (internal to the DSP megamodule).

The IDMA.IDMA1\_COUNT[16] FILL bit defines whether this is a transfer from memory to memory or if this is a solid-color fill.

An IDMA1 transfer where IDMA.IDMA1\_COUNT[16] FILL = 0 copies IDMA.IDMA1\_COUNT[15:2] COUNT bytes from the address defined in the IDMA.IDMA1\_SOURCE register to the address defined in the IDMA.IDMA1\_DEST register. The addresses must be aligned on word (4-byte) boundaries. The byte count must be a multiple of 4 bytes.

The IDMA.IDMA1\_COUNT[28] INT register bit enables the IDMA\_INT1 interrupt (Evt 14; for information about generation on completion of the IDMA1 transfer, see [Table 14-3](#)). By default, no interrupt is generated.

When conflicts occur, the IDMA.IDMA1\_COUNT[31:29] PRI bit field defines the priority of the IDMA transfer with respect to DSP and DMA/HOST accesses.

The memory paging programming example follows:

- IDMA1\_SOURCE = &mySrcTable[0]; // mySrcTable aligned on word boundary
- IDMA1\_DEST = &myDstTable[0]; // myDstTable aligned on word boundary
- IDMA1\_COUNT = (IDMA1\_COUNT & ~(0xFFFC)) | size of (mySrcTable);
- IDMA1\_COUNT = (IDMA1\_COUNT & ~(116)) | 016; // copy mode
- IDMA1\_COUNT = (IDMA1\_COUNT & ~(128)) | 028; // no interrupt
- IDMA1\_COUNT = (IDMA1\_COUNT & ~(0x729)) | 0x729; // low priority

An IDMA1 transfer where IDMA.IDMA1\_COUNT[16] FILL = 1 replicates the IDMA.IDMA1\_SOURCE word as many times as defined in IDMA. An IDMA1\_COUNT.COUNT (count divided by 4) to the address defined in the IDMA.IDMA1\_DEST destination address must be aligned on word (4-byte) boundaries. The byte count must be a multiple of 4 bytes.

The solid-color copy (SSC) programming example follows:

- IDMA1\_SOURCE = my32bPattern; // 32b pattern to be replicated
- IDMA1\_DEST = &myDstTable[0]; // myDstTable aligned on word boundary
- IDMA1\_COUNT = (IDMA1\_COUNT & ~(0xFFFC)) | size of (mySrcTable);
- IDMA1\_COUNT = (IDMA1\_COUNT & ~(116)) | 116; // SCC mode
- IDMA1\_COUNT = (IDMA1\_COUNT & ~(128)) | 028; // no interrupt
- IDMA1\_COUNT = (IDMA1\_COUNT & ~(0x729)) | 0x729; // low priority

---

**NOTE:** Because the IVA2.2 subsystem is typically configured (recommended for video applications) so that L1D has memory-mapped SRAM, IDMA1 is normally used only for L1D>L1D fast copy.

---

#### 14.4.4.3 Programming an EDMA Transfer

Programming a complete EDMA transfer requires the following steps:

1. Define the logical channel(s).
2. Prioritize the defined transfer (with respect to other defined transfers).
3. Start the transfer.
4. Review the progression and completion of the transfer.

#### 14.4.4.4 Defining a Logical Channel

##### 14.4.4.4.1 Single Logical Channel Definition

A complete EDMA transfer can be defined by one or several chained and/or linked logical channels.

Up to 128 independent contexts, each fully defining a logical channel, can be defined. These 128 contexts correspond to the 128 PaRAM entries available in the IVA2.2 subsystem. For more information about these PaRAM entries, see [Section 14.3.2.1.1.3, DMA/QDMA Channel Mapping and PaRAM Entry](#), and the corresponding [Figure 14-13](#).

Logical channel definition relies on the following:

- Base addresses:
  - PARAM[LCH#].SRCi: 32-bit source address
  - PARAM[LCH#].DSTi: 32-bit destination address

- Transfer sizes:

Transfer size is common to source and destination. A transfer can be constituted on a 3-dimensional array; C is an array of CCNT arrays, each composed of BCNT arrays, each composed of ACNT bytes:

- PARAM[LCH#].ACNT: Number of bytes in the A array (from 0 to 65,535)
- PARAM[LCH#].BCNT: Number of A arrays in the B array (from 0 to 65,535)
- PARAM[LCH#].CCNT: Number of B arrays in the C array (from 0 to 65,535)

---

**NOTE:** Setting one of the ACNT, BCNT, or CCNT arrays to 0x0 prevents a transfer from being submitted to one of the physical channels (assuming that the compatibility mode is not set; see Kelvin DMA compatibility mode).

---

- PARAM[LCH#].BCNTRLD: BCNT reload value when BCNT reaches 0 (from 0 to 65,535)

---

**NOTE:** When programming CCNT>1, programming PARAM[LCH#].BCNTRLD to be equal to PARAM[LCH#].BCNT is recommended.

---

- Indexes between dimensions:

- PARAM[LCH#].SRCBIDX: Index between A arrays at source (from -32,768 to 32,767)
- PARAM[LCH#].SRCIDX: Index between B arrays at source (from -32,768 to 32,767)
- PARAM[LCH#].DSTBIDX: Index between A arrays at destination (from -32,768 to 32,767)
- PARAM[LCH#].DSTCIDX: Index between B arrays at destination (from -32,768 to 32,767)

---

**NOTE:** Programming the logical channel does not automatically start it. See [Section 14.4.4.6.1, Assigning a Logical Channel to a Trigger Event](#).

---

- Addressing modes:

- PARAM[LCH#].OPT[0] SAM: source addressing mode (0: post-incremented; 1: constant)
- PARAM[LCH#].OPT[1] DAM: destination addressing mode (0: post-incremented; 1: constant)

---

**NOTE:** Constant addressing mode is supported only from/to IVA2.2 DSP megamodule memories, not from/to device memories and peripherals. This can be replaced by using a post-increment addressing mode and an index equal to 0.

---

**Example:**

```
/* ----- */
/*fills dstArray with cstValue values (w/o constant AM) */
/* ----- */
```

```
PARAM[LCH#].SRC = &cstValue;
PARAM[LCH#].DST = &dstArray[0];
PARAM[LCH#].ACNT = sizeof(int);
PARAM[LCH#].BCNT = sizeof(dstArray) / sizeof(int);
PARAM[LCH#].CCNT = 1;
PARAM[LCH#].SRCBIDX = 0;
PARAM[LCH#].DSTBIDX = sizeof(int);
PARAM[LCH#].OPT.SAM = 0;
PARAM[LCH#].OPT.DAM = 0;
```

#### 14.4.4.2 Controlling Submission Granularity

The logical channel (when triggered) can split a transfer into several requests submitted to one of the physical channels. The physical channel supports submitted requests of up to two dimensions, meaning that a 3-dimensional transfer is always split into (at least) 2-dimensional transfers. The user can also program the logical channel so that submitted requests are 1-dimensional transfers; for example:

- PARAM[LCH#].SYNCDIM = 0; // submitted transfers are maximum 1D.
- PARAM[LCH#].SYNCDIM = 1; // submitted transfers are maximum 2D.

#### 14.4.4.3 Linking to Another Logical Channel

A logical channel can be programmed so that on its completion another context is copied from another logical channel. This is useful because the logical channel is used as a working set during the DMA transfer, meaning that initial context configuration is lost after the associated transfer completes.

- PARAM[LCH#].LINK = linkLCH# << 5

The LINK value is the base address of the linked logical channel context.

When the LINK value is set to 0xFFFF, no context is loaded for that logical channel:

- PARAM[LCH#].LINK = -1

---

**NOTE:** Only the context is copied, and the logical channel is not automatically restarted on link. Restarting a logical channel that just received its new context occurs only after a trigger event associated with that logical channel is detected. See [Section 14.4.4.6.1, Assigning a Logical Channel to a Trigger Event](#).

---

#### 14.4.4.4 Chaining Logical Channel

A logical channel can be programmed so that on its total or partial completion, another logical channel is started. This is useful for defining a series of transfers with different contexts as a complete DMA transfer. The main advantage is that the overhead to program all the chained transfers is shared among all channels.

- Partial completion chaining

After the submitted section (see [Section 14.4.4.2, Controlling Submission Granularity](#)) of a logical channel is complete, a programmable completion code is returned. If partial completion chaining is enabled in the context of the logical channel, this completion code defines which trigger event is set. The logical channel associated with that trigger event is automatically submitted. See [Section 14.4.4.6.1, Assigning a Logical Channel to a Trigger Event](#).

To chain a logical channel LCHi to LCHj, so that LCHj is automatically started after each LCHi submission to a physical channel has completed:

- PARAM[LCHi].OPT.TCC = trigEvtX; // trigEvtX: trigger event number
- PARAM[LCHi].OPT.ITCCHEN = 1
- DCHMAP[trigEvtX] = LCHj

- Total completion chaining

After all submitted parts of a logical channel are complete, programmable completion code is returned. If total completion chaining is enabled in the context of the logical channel, this completion code defines which trigger event is set. The logical channel associated with that trigger event is automatically submitted. See [Section 14.4.4.6.1, Assigning a Logical Channel to a Trigger Event](#).

For example, to chain a logical channel LCHi to LCHj so that LCHj is automatically started after LCHi has completed:

- PARAM[LCHi].OPT.TCC = trigEvtX; // trigEvtX: trigger event number
- PARAM[LCHi].OPT.TCCHEN = 1
- DCHMAP[trigEvtX] = LCHj

## 14.4.4.5 Prioritizing Defined Transfers

### 14.4.4.5.1 Mapping Between DMA/QDMA Events and Event Queues

The assignment of 64 DMA and 8 QDMA channels to two event queues of the channel controller is achieved by configuring the DMA queue number registers ([TPCC\\_DMAQNUM0](#) and [TPCC\\_DMAQNUM1](#)) and the QDMA queue number register ([IVA\\_TPCC.QDMAQNUM](#)). When an event is selected for submission, it is queued in the user-defined event queue. This typically defines a 2-level priority preemption scheme, as queues are usually mapped to different transfer controllers.

### 14.4.4.5.2 Mapping a Queue to a Transfer Controller

Events at the head of an event queue define which logical channel (Param Entry) is selected for submission to the associated physical channel (transfer controller). The association between an event queue and a physical channel can be defined in the [TPCC\\_QUETCMAP](#) register. By default, TPTC0 is associated with event queue 0, and TPTC1 is associated with event queue 1. This mapping is a static decision; it does not change during DMA operation.

---

**NOTE:** TPTC0 and TPTC1 are not symmetrical; their numbers are just inverted, compared to the Davinci device. To improve compatibility with Davinci devices, invert the mapping of the event queue to the transfer controller, as shown below:

`QUETCMAP = (QUETCMAP & ~0xFF) | 0x10;`

Typically, this is used to allow submission-time preemption, so that by example:

- Event queue 0 is used for background, potentially long, not very latency-sensitive, not very critical DMA transfers.
  - Event queue 1 is used for short, latency-sensitive, or critical (for example, hardware synchronized) DMA transfers.
- 

### 14.4.4.5.3 Handling Priority

In IVA2.2 local interconnect arbitration, priority of individual bus requests for a DMA transfer over other DMA- or CPU-initiated bus requests is defined by the event queue to which the event associated with the transfer is submitted. This can be configured per event queue in the [TPCC\\_QUEPRI\[2:0\]](#) PRIQ0 and [TPCC\\_QUEPRI\[6:4\]](#) PRIQ1 bit fields. By default, event queues 0 and 1 have the same priority (highest possible priority is 0x0).

CPU bus-requests priority is defined in the [IDMA.MDMAARBE\[18:16\]](#) PRI bit field. By default, the CPU has the lowest possible priority (0x7).

Typically, this is used to allow transfer-time preemption, so that, for example, bus requests associated with event queue 1 are served ahead of event queue 0 or CPU requests.

Example:

- `// DMA#0->0x7 (lowest), DMA#1->0x0 (highest), CPU->0x4 (mid)`
- `QUEPRI = (QUEPRI & ~0xFF) | 0x07;`
- `MDMAARBE = (QUEPRI & ~(0xF16)) | 0x4 16;`

### 14.4.4.5.4 Aged Priority

To prevent having a DMA request stalled for a very long time, the IVA2.2 implements an aged priority scheme (also referred to as an inversion priority scheme) on the DMA ports to change the priority defined in the [TPCC\\_QUEPRI](#) register. This is done by regularly decreasing the priority level (increasing priority in arbitration) of a stalled request. The interval between two consecutive updates of the priority level is defined in the [SYSC\\_LICFG1](#) register. By default, the aged priority scheme is disabled ([SYSC\\_LICFG1=0x0](#)), and arbitration priority is dictated by programmed values in [QUEPRI](#) and [MDMAARBE](#).

#### 14.4.4.5.5 Optimizing 2D Transfers

IVA2.2 EDMA can be configured so that DMA 2D transfers are optimized, allowing for large bursts to be generated to the SDRAM. This optimization has no effect on transfers issued as 1D transfers to the physical channels. This is recommended to enable that feature when the sources or destinations of the 2D transfers are the VRFB (SDRAM tiling structure).

To fully benefit from the optimization and disable MMU page-crossing checks:

- Large MMU page(s) are defined for the VRFB view(s) (typically 16MB supersection).
- The user software ensures that a 2D transfer does not span MMU large pages.

With the preceding conditions, use the following settings to use the IVA2.2 2D burst optimization:

- IVA\_SYSC.SYSC\_LICFG0.DMA2DOPTEN = 1
- IVA\_SYSC.SYSC\_LICFG0.PAGEXINGEN = 1

---

**NOTE:** The user software must ensure that a 2D transfer never spans MMU page boundaries. The reason for IVA\_SYSC.SYSC\_LICFG0.PAGEXINGEN = 1 is to remove the hardware check mechanism of 2D bursts crossing MMU pages. A 2D burst that spans these boundaries can lead to undefined behavior. PAGEXINGEN = 0 prevents such situations through hardware.

---

#### 14.4.4.6 Starting the Transfer

Before starting the transfer, a trigger event must be associated with the logical channel. Three modes trigger a DMA transfer:

- Manual trigger (software-synchronized transfers)
- Hardware trigger (hardware-synchronized transfers)
- Automatic trigger (automatic on-submission transfer start)

##### 14.4.4.6.1 Assigning a Logical Channel to a Trigger Event

The 64 DMA channels and the 8 QDMA channels can be flexibly mapped to any of the 128 available PaRAM entries (see [Figure 14-13](#)).

Any of the 64 DMA channels can be mapped to any of the 128 PaRAM entries through DMA channel-mapping registers [TPCC\\_DCHMAP<sub>i</sub>](#) ( $i = 0$  to 63).

Any of the 8 QDMA channels can be mapped to any of the 128 PaRAM entries through QDMA channel-mapping registers [TPCC\\_QCHMAP<sub>j</sub>](#) ( $j = 0$  to 7).

##### 14.4.4.6.2 Manual Trigger (Software-Synchronized Transfers)

When a logical channel is defined and prioritized, the user can assign the logical channel (or the first in the chained list) to a trigger event (from 0 to 63) by writing the number of the logical channel (PaRAMEntry #) to one of the DMA channel-mapping registers [TPCC\\_DCHMAP<sub>i</sub>](#) ( $i = 0$  to 63). Then, the user can manually start the transfer (one logical channel or a chained list of logical channels) by writing 1 to the bit in the [TPCC\\_ESR](#) or [TPCC\\_ESRH](#) register associated with the trigger event of the logical channel (or the first logical channel in the chained list).

---

**NOTE:** The event does not need to be enabled in the [TPCC\\_EER](#) register to be manually triggered.

---

Example:

```
/* ----- */
/*To manually start defined logical channel #0x3, uses event #20 */
/* ----- */
DCHMAP[20] = (DCHMAP[20] & ~(0x1FF<<5)) | 0x3<<5;
ESR = 1 << 20;
```

#### 14.4.4.6.3 Hardware Trigger (Hardware-Synchronized Transfers)

When a logical channel is defined and prioritized, the user can assign the logical channel (or the first in the chained list) to a trigger event (from 0 to 19) by writing the number of the logical channel (PaRAMEntry #) to one of the DMA channel-mapping registers `TPCC_DCHMAPi` ( $i = 0$  to 19). The user can allow this logical channel to be triggered by an associated hardware DMA request by writing 1 in the associated bit of the EER register. The mapping of a hardware DMA request to DMA events is fixed. The mapping of DMA requests to device peripheral sources is listed in [Table 14-2](#).

Example:

```
/* ----- */
/* Associate defined logical channel #0x5 to UART3_DMA_TX*/
/* UART3_DMA_TX is DMA request #10 and associated to evt #10 */
/* ----- */
DCHMAP[10] = (DCHMAP[10] & ~(0x1FF<<5)) | 0x5<<5;
```

#### 14.4.4.6.4 Automatic Trigger (QDMA)

The user can specify a trigger word from among any of the eight 32-bit words of the logical channel context (PaPARAM entry) for QDMA. Writing to the trigger word triggers the channel controller of QDMA to issue a transfer request. The trigger word field of the QDMA channel mapping register `TPCC_QCHMAPj` (where  $j = \{0$  to 7}) defines the trigger word for a particular QDMA channel, as shown in [Figure 14-13](#).

This flexibility enables the CPU to selectively modify only the PaPARAM entry that requires modification, and thereby trigger the transfer. For example, after a transfer, if only count must change, QCHMAP can be configured so that count is the trigger word, and a write to it automatically triggers the transfer.

Example:

```
/* ----- */
/* Associate defined logical channel #0x5 to QDMA #1 */
/* ----- */
QCHMAP[1] = (QCHMAP[1] & ~(0x1FF<<5)) | 0x5<<5;
/* ----- */
/* Define DST parameter (0x3) to be trigger word of LCH */
/* ----- */
QCHMAP[1] = (QCHMAP[1] & ~(0x7<<2)) | 0x3<<2;
```

In addition, the IDMA can be used to offload the CPU of the DMA configuration. See [Section 14.4.4.6.5, Offloaded Configuration \(Using IDMA\)](#).

#### 14.4.4.6.5 Offloaded Configuration (Using IDMA)

The IVA2.2 allows quick programming of DMA transfers by offloading the CPU of most of the DMA transfer issue time. To do so, the user typically maintains a copy of the logical channel contexts (PaPARAM entries) in L1D SRAM. A CPU update of a logical channel context is very fast in L1D SRAM. After completing a logical channel context update, the CPU can page the context from L1D to DMA PaPARAM entries using another simple DMA, internal-to-DSP megamodule (IDMA). For example:

```
disable_interrupts();
while(IDMA0_STATUS & 0x3);// previous IDMA completion/*
----- */
/* Update of logical channels definition table in L1D */
/* ----- */
LCTable->OPT = opt;
LCTable->SRC = src;
LCTable->ACNT = num_bytes;
```

```

LCTable->BCNT = num_arrays;
LCTable->DST = dst;
LCTable->DSTBIDX = dbidx;
LCTable->SRCBIDX = sbidx;
LCTable->LINK = 0xFFFF;
LCTable->BCNTRLD = bcntrld;
LCTable->DSTCIDX = dcidx;
LCTable->SRCCIDX = scidx;
LCTable->CCNT = num_frames;
/* ----- */
/* initiate IDMA transfer */
/* ----- */
IDMA0_SOURCE = &LCTable[0];
IDMA0_DEST = &PaRAM[0];
IDMA0_MASK = 0xFFFFFFF00;
IDMA0_COUNT = 0x0;
enable_interrupts();

```

#### 14.4.4.6.6 Direct Configuration to Transfer Channel (Not Recommended)

The registers of the physical channels are memory-mapped, primarily to enable, clear, and read status for error interrupts generated by the physical channel. For more information, see [Section 14.4.10, Error Identification Process](#).

It is possible to write directly to other control registers of the physical channels and issue a transfer; however, this is not recommended and therefore is not described here.

---

**NOTE:** This can work safely only if the DMA controller is not used.

---

#### 14.4.4.6.7 DMA Completion Mode

The IVA2.2 EDMA defines when a DMA transfer is complete:

- Early completion: All associated transfers were submitted to the physical channel. Early completion does not ensure that transfer is complete in end memory.
  - PARAM[LCHi].OPT.TCCMODE = 1
- True completion: All associated transfers were submitted to the physical channel, and all those transfers are complete, from the physical channel standpoint. True completion ensures that transfer is complete in end memory.
  - SYSC.SYSC\_LICFG0.DMATRUECOMPEN = 1; // is statically set.
  - PARAM[LCHi].OPT.TCCMODE = 0

---

**NOTE:** TCCMODE = 0 does not ensure that transfer is complete in end memory if DMATRUECOMPEN = 0.

---

By default, DMATRUECOMPEN = 0. This is recommended to statically set DMATRUECOMPEN.

True completion is typically used when the IVA2.2 DMA is the producer of a buffer shared with another master processor or a DMA (consumer). A completion message is sent to the consumer only after the DMA transfer is complete.

Completion mode affects timing for the following actions:

- IPR/IPRH bit update (for polling scheme)
- Interrupt generation (for interrupt scheme)
- CER/CERH bit update (for chaining)

#### 14.4.4.6.8 Partial Versus Total Completion

DMA can be programmed so that IPR bit update and interrupt generation occur:

- After each submission to the physical channel is complete
- After the last submission to the physical channel is complete

##### Partial completion interrupt

After the submitted section (see [Section 14.4.4.4.2, Controlling Submission Granularity](#)) of a logical channel is complete, a programmable completion code is returned. If a partial completion interrupt is enabled in the context of the logical channel, this completion code defines which IPR bit is set.

For example, to allow IPR to be updated (and possibly an interrupt to be generated) after each LCHi submission to a physical channel is complete:

- PARAM[LCHi].OPT.TCC = intEvtx; // intEvtx: IPR bit to be updated
- PARAM[LCHi].OPT.ITCINTEN = 1

##### Total completion interrupt

After all submitted parts of a logical channel are complete, a programmable completion code is returned. If a total completion interrupt is enabled in the context of the logical channel, this completion code defines which IPR bit is to be set.

For example, to allow IPR to be updated (and possibly an interrupt to be generated) after all LCHi submissions to a physical channel are complete:

- PARAM[LCHi].OPT.TCC = intEvtx; // intEvtx: IPR bit to be updated
- PARAM[LCHi].OPT.TCINTEN = 1
  - By polling
  - By interrupt

#### 14.4.4.6.9 Tracking DMA Completion

There are two ways to track DMA completion:

- Polling the completion register when the estimated completion time has elapsed
- Enabling completion interrupts

##### Polling example (total completion)

- PARAM[myLCH].OPT.TCINTEN = 1; // total interrupt completion bit update
- PARAM[myLCH].OPT.ITCINTEN = 0; // no partial interrupt completion bit update
- PARAM[myLCH].OPT.TCC = myTCC
- // myTCC does not contribute to interrupt generation (polling mode)
- IER = (IER & ~(1<<myTCC)) | 0<<myTCC
- // start transfer
- DCHMAP[myEvt] = (DCHMAP[myEvt] & ~(0x1FF<<5)) | myLCH<<5
- ESR = 1 << myEvt
- // do something useful (that does not depend on DMA completion)
- // poll IPR bit
- while( !(IPR & (1<<myTCC)) ); // polls for completion

##### Interrupt example (total completion)

- disable\_interrupts()

- PARAM[myLCH].OPT.TCINTEN = 1; // total interrupt completion bit update
- PARAM[myLCH].OPT.ITCINTEN = 0; // no partial interrupt completion bit update
- PARAM[myLCH].OPT.TCC = myTCC
- // myTCC does contribute to interrupt generation (polling mode)
- IER = (IER & ~(1<<myTCC)) | 1<<myTCC
- INTMUX[0] = (INTMUX[0] & ~(0x7F)) | 0x1D; // map CPU it #4
- CPU.IER = (CPU.IER & (1<<4)) | 1<<4; // unmask CPU it #4
- enable\_interrupts()
- // start transfer
- DCHMAP[myEvt] = (DCHMAP[myEvt] & ~(0x1FF<<5)) | myLCH<<5
- ESR = 1 << myEvt
- // do something useful (that does not depend on DMA completion)
- // this code is interrupted when DMA completes

#### 14.4.4.6.10 DMA Interrupt Service Routine

The channel controller does not generate a new interrupt signal for new pending interrupts if the user did not clear previous pending interrupts. There are two options for constructing an ISR for DMA. The first is to poll all the bits during execution of the ISR, and to clear all enabled bits in an interrupt-pending register by writing to the interrupt-pending clear (ICR/ICRH) register before exiting any ISR. Pseudo-code for this option follows:

1. Enter ISR.
2. Read [TPCC\\_IPR](#).
3. For the condition set in [TPCC\\_IPR](#),
  - (a) Perform operation as needed.
  - (b) Clear bit for serviced INT.
4. Read IPR.
  - (a) If [TPCC\\_IPR](#) = 0, exit ISR.
  - (b) If [TPCC\\_IPR](#) = 1, go to Step 3.

The second option is to service the ISR and then, before exiting the ISR, to write to the EVAL bit of the IEVAL register. This forces the EDMA channel controller to generate a new interrupt signal if there are still pending interrupts in the interrupt-pending register (IPR/IPRH). Pseudo-code for this ISR option follows:

1. Enter ISR.
2. Read [TPCC\\_IPR](#).
3. For the condition set in [TPCC\\_IPR](#),
  - (a) Perform operation as needed.
  - (b) Clear bit for serviced INT.
4. Read IPR.
  - (a) If [TPCC\\_IPR](#)=0, exit ISR.
  - (b) If [TPCC\\_IPR](#)=1, set the [TPCC\\_IEVAL](#).EVAL bit to force triggering a new interrupt.

#### 14.4.4.6.11 Benchmarking

The DMA channel controller monitors the number of event entries in an event queue to determine whether they exceed the user-programmed threshold. The queue threshold for each event queue can be programmed in the [TPCC\\_QWMTHRA](#) and [TPCC\\_QWMTHRB](#) registers. When the number of event entries in an event queue exceeds the user-programmed threshold, a queue threshold error occurs. This error is captured in the THRXCD field of event-queue status register [TPCC\\_QSTATI](#) (I = 0 or 1) and in the QTHRXCDn field in the [TPCC\\_CCERR](#) register.

**Instruction type:** Single-cycle

**Delay slots:** 0

**See also:** EFRW

### EFRW *Receive Word From EFI*

**Syntax:** EFRW (.unit) dst

.unit = .S1, .S2

**Compatibility:** C64x+ CPU only

**Opcode:**

3 1		2 9	2 8	2 7				2 3	2 2				1 8	1 7				1 3	1 2	1 1						6	5	4	3	2	1	0	
0	0	0	0		dst			0	0	0	0	0	0	0	1	1	1	1	0	0	1	1	1	1	0	0	0	1	0	0	0	s	p

Opcode map field used...	For operand type...	Unit
dst	int	.S1,.S2

**Description:** A 32-bit data value is read from the EFI and is written to dst. There is an A-side EFI and a B-side EFI. The side used is determined by the S unit that is selected. There is no cross-path capability; A-side receives must go to an A-file register pair, and B-side receives must go to a B-file register pair. This instruction executes unconditionally; that is, it cannot be predicated.

The ready signal is sampled in the DS phase of the EFRW instruction and will cause the CPU to stall before the EFRDW instruction reaches E1 if the data to be read has not yet been registered in the CPU.

**Execution:**

if(.S1)                    A\_EFI\_Din[31:0] → dst (A0 – A31)  
 else // .2                B\_EFI\_Din[31:0] → dst (B0 – B31)

**Instruction type:** Single-cycle

**Delay slots:** 0

**See also:** EFRDW

### EFSDW *Send Double Word to EFI*

**Syntax:** EFSDW (.unit) src1, src2, dst

.unit = .L1, .L2

**Compatibility:** C64x+ CPU only

**Opcode:**

3 1		2 9	2 8	2 7				2 3	2 2				1 8	1 7				1 3	1 2	1 1							5	4	3	2	1	0
	creg		z		dst			src2			src1			x	0	1	1	1	1	0	1	0	1	0	1	1	0	0	s	p		

```

if(cond)
if(.L1)          src2 → A_EFI_Dout[31:0]
                 ucst5 → A_EFI_Scmd[4:0]
else // .L2     src2 → B_EFI_Dout[31:0]
                 ucst5 → B_EFI_Scmd[4:0]
else           nop
  
```

**Instruction type:** Single-cycle

**Delay slots:** 0

**See also:** EFSDW

### 14.4.5.3 C64x+ EFI Use in IVA2.2

The following programming model describes how to write and read a register using the EFI. In the context of IVA2.2, only the EFSW, EFRW, and EFSDW instructions are used.

#### 14.4.5.3.1 Read Registers Using the EFI Programming Model

To read a 32-bit value in a video accelerator register using the EFI, the following sequence must be used:

```

EFSW address_32b, opcode_5b
NOP N
EFRW cpu_reg
  
```

With:

- address\_32b is the video accelerator address of the register from which the value must be read.
- opcode\_5b is used to code the read operation: 0x02.
- N is the number of cycles to wait data is written in the EFI FIFO. In the context of IVA2.2 N = 0x22.
- Cpu\_reg is the 32-bit CPU register where the read value is stored.

---

**NOTE:** To avoid handling specific cases of successive read requests, interrupts are disabled between the time the EFSW is issued and the data is retrieved in the DSP register.

---

**NOTE:** When it is necessary to read a large number of registers, the two macros that correspond to the two instructions given previously can be used to allow issuing a read request while reading data:

- EFSW address\_32b, opcode\_5b: IME\_SendReadReq(unsigned ime\_addr\_reg)
- EFRW cpu\_reg: IME\_ReceiveData()

In that case, there is no need to insert a NOPs instruction between the two EFI commands. Read latency is under CPU control.

---

#### 14.4.5.3.2 Write Registers Using the EFI Programming Model

To write a 32-bit value in a video accelerator register using the EFI, the following instruction must be used:

```

EFSDW value_32b, address_32b, opcode_5b
  
```

With:

- The value\_32b register contains the 32-bit word to write.
- address\_32b is the video accelerator address of the register in which value must be written.
- opcode\_5b is used to code the write operation: 0x01.

---

**NOTE:** The address is stored in the even 32-bit register of the 64-bit register pair, while value\_32b is stored in the odd register (that is, the MSB part).

---

## 14.4.6 iME and iLF Basic Programming Model

### 14.4.6.1 Typical Use

The iME and iLF coprocessors are parallel coprocessors, so they are partially autonomous and provide highly parallel video processing. To use the iME/iLF coprocessor in a video accelerator design, perform the following steps:

- Step 1. Initialize the module.
- Step 2. Prepare the data to be processed in the shared L2 memory.
- Step 3. Prepare the instructions for processing in the L2 memory.
- Step 4. Prepare the parameter stack in the L2 memory.
- Step 5. Configure the device to generate an interrupt on completion.
- Step 6. Write a LoadInstBuf() instruction in the program buffer register ([iME\\_PROGRAMBUFFERLINENLSBi](#) and [iME\\_PROGRAMBUFFERLINENMSBi](#) or [iLF\\_PROGRAMBUFFERLINENLSBi](#) and [iLF\\_PROGRAMBUFFERLINENMSBi](#)) with the address parameter pointing to the instruction in L2 shared memory.
- Step 7. Start the coprocessor by writing to START in the [iME\\_COMMANDREG](#) or [iLF\\_COMMANDREG](#) register.
- Step 8. Wait for the coprocessor interrupt (the DSP or sequencer is free to perform other tasks during coprocessor processing).

Steps 2, 3, and 4 can be performed with the help of the DSP EDMA, which can be configured by both the sequencer and the DSP megamodule.

Steps 5, 6, and 7 can be performed by both the sequencer and the DSP megamodule, but using the DSP megamodule for this task causes long DSP stalls because of high latency between the DSP megamodule and the iLF/iME module.

The DSP megamodule or the sequencer can prepare multiple sets of data in shared L2 memory (Steps 2, 3, and 4), then the sequencer can launch multiple processing with the coprocessor (Steps 6 and 7) until all prepared data sets in shared L2 memory are used. This way, the DSP and/or DSP EDMA is offloaded for a longer time. [Figure 14-38](#) is a flowchart of a typical use of iLF/iME in video processing. In the flowchart, the four units (DSP, EDMA, sequencer, and coprocessor) work in parallel.

## 14.4.7 Interrupt Management

### 14.4.7.1 Interrupt Flow in IVA2.2 Subsystem

The DSP megamodule interrupt controller (IC) detects, combines, and routes up to 128 system events (internal and external) to the 12 DSP CPU interrupt lines. For more information about interrupt mapping of the IVA2.2 subsystem (internal and external interrupts), see [Table 14-3](#).

In addition to performing handshaking for chip-level wake-up sequencing for waking from static power-down, the DSP megamodule WUGEN module internally routes the interrupt request to the IC module. This occurs because the WUGEN module is the only DSP megamodule module in the CORE power domain to enable the powered-off DSP subsystem to be awakened after the DSP receives an interrupt from any device peripherals.

[Figure 14-39](#) shows the IVA2.2 subsystem interrupt flow with the main WUGEN and IC registers used for event generation.

Figure 14-39. IVA2.2 Interrupt Flow

iva22-040

**NOTE:** The CSR/TCR, IER, IFR, and ICR registers belong to the DSP CPU block (C64x+). For more information, see the C64x+ documentation ([Section 14.3.1.8](#)).

#### 14.4.7.2 Event Combined Programming Sequence

In addition to generating a combined interrupt based on programmable event combinations, the event combiner provides a masked view of the event flag registers. By reading the masked event flag (IVA\_IC.MEVTFLAG<sub>i</sub> where  $i = \{0 \text{ to } 3\}$ ) registers, the DSP CPU sees only the event flags pertaining to the corresponding combined event (EVT<sub>x</sub> with  $x = \{0, 1, 2, 3\}$ ).

When servicing a combined interrupt, perform the following steps:

1. Read the IVA\_IC.MEVTFLAG<sub>i</sub> register corresponding to the combined event EVT<sub>x</sub> (where  $i = \{0 \text{ to } 3\}$ ).
2. Check the pending events.
3. Write the value of the IVA\_IC.MEVTFLAG<sub>i</sub> register into the IVA\_IC.EVTCLR<sub>x</sub> register (where  $i = \{0 \text{ to } 3\}$ ).
4. Service the received interrupts.
5. Repeat steps 1 through 4 until IVA\_IC.MEVTFLAG<sub>i</sub> = 0x0 (where  $i = \{0 \text{ to } 3\}$ ).

This clears only those events combined on EVT<sub>x</sub>. Any events masked in the IVA\_IC.EVTMASK<sub>i</sub> register (where  $i = \{0 \text{ to } 3\}$ ) do not need to be cleared if set in the IVA\_IC.EVTFLAG<sub>i</sub> register (where  $i = \{0 \text{ to } 3\}$ ) (they can generate an exception or are used as event outputs).

Before returning, the DSP CPU should repeat steps 1 through 4 until no pending events are found. This ensures that any events received during the ISR are captured. If an event EVT<sub>x</sub> is received at the same time that its flag is being cleared in the IVA\_IC.EVTCLR<sub>i</sub> register (where  $i = \{0 \text{ to } 3\}$ ), it does not clear. Repeating steps 1 through 4 ensures that no events are missed.

#### 14.4.7.3 Event <-> Interrupt Mapping Programming Sequence

The INTC allows programming independently which of the 128 inputs events is mapped to each DSP CPU interrupt by writing the event number in the bit field corresponding to the CPU interrupt in the IC.INTMUX<sub>j</sub> registers (where  $j = \{1 \text{ to } 3\}$ ).

Example:

```

/* ----- */
/*evtTable has the 12 evt <-> CPU interrupt mapping */
/* ----- */
evtTable[0] = 55; // Mailbox event highest priority
evtTable[1] = 61; // McBSP1TX event
[...]
evtTable[11] = 29; // EDMA3 gbl completion event lowest priority
for(I=0; i<12; I++) { // for each CPU maskeable interrupt
INTMUX(I >> 2 + 1) |= (evtTable[i] & 0x7F) << ((I & 0x3) << 3);
}

```

#### 14.4.7.4 Interrupt Exception Programming Sequence

The INTC can generate a system event (INTERR) that is internally routed to system event input EVT96. This event is generated when a DSP CPU interrupt is dropped (that is, when a DSP CPU interrupt is received while the interrupt flag is already set in the DSP CPU).

This can inform the user of possible problems in the software code, such as whether interrupts were disabled for an extended period of time, or whether pipelined (noninterruptible) code sections were too long.

---

**NOTE:** Because the interrupt drop detection logic is in the CPU, only interrupts sourced from a single system event can be detected. The dropping of individual combined events is not possible, although dropping the output of an event combiner is possible. Only the first dropped interrupt detected is reported by the INTERR event.

---

The IVA\_IC.INTXSTAT register holds the ID of the CPU interrupt and the system event number of the dropped event. By setting the IVA\_IC.INTXCLR[0] CLEAR bit to 1, the software user resets the IVA\_IC.INTXSTAT register to 0.

When servicing the interrupt exception, the CPU performs three steps:

1. Reads the IVA\_IC.INTXSTAT register
2. Checks the error condition
3. Clears the error through the IVA\_IC.INTXCLR register

The dropped events that generate the INTERR event (EVT96) can be qualified by a mask register. CPU interrupts that are to be ignored by the drop detection hardware can be masked in the IVA\_IC.INTDMASK register.

#### 14.4.7.5 Interrupt Controller Basic Programming Model for Power Down of IVA2.2 Subsystem

When going to a low-power state not involving IVA2.2 logic power off, there are no special software settings to perform. In particular, the noncombined interrupts can be used without any specific handling for that power transition. To run the procedure for a correct transition to power-down state not involving logic-off, the user must perform the following sequence:

1. Ensure that all wake-up events are correctly mapped to enabled DSP CPU interrupts, and are unmasked in combined event registers (if combined events are used).
2. Clear associated bits in the WUGEN\_MEVT0 and WUGEN\_MEVT1 register to unmask wake-up interrupts.

---

**NOTE:** Software must not unmask in the WUGEN module an event that is not correctly mapped to an enabled DSP CPU interrupt. If that event is triggered, the IVA2.2 subsystem exits the power-down state but does not wake up.

---

The user must program the following procedure when transitioning to the (logic) power-off state (OFF state for device):

1. Ensure that all wake-up events are correctly mapped to enabled DSP CPU interrupts, and are unmasked in combined event registers (if combined events are used).
2. Clear correct bits in the WUGEN\_MEVT0 and WUGEN\_MEVT1 registers to unmask wake-up interrupts.
3. Save necessary context (all except interrupt-related registers).

---

**NOTE:** Steps 3 through 5 are automatic, but interruptible. If a wake-up interrupt occurs at this stage, the transition to power down is canceled and the next transition restarts from the beginning. Software tip: A software variable (semaphore) can be set in Step 3, modified in all calls of the wake-up interrupt ISR routine, and checked before executing the IDLE instruction in Step 5. For a complete description of the DSP CPU ISR register, see the C64x+ documentation (Section 14.3.1.8).

---

4. Save the interrupt configuration in:
  - (a) IVA\_IC.INTMUXj register (where j = {1 to 3})
  - (b) IVA\_IC.EVTMASKi register (optional, where i = {0 to 3})
  - (c) IVA\_IC.INTDMASK register (optional)
  - (d) DSP CPU IER register. See the C64x+ documentation for IER register description (Section 14.3.1.8).
5. Execute the DSP IDLE instruction.

---

**NOTE:** Software must not unmask in the WUGEN module an event that is not correctly mapped to an enabled DSP CPU interrupt. If that event is triggered, the IVA2.2 subsystem exits the power-down state but does not wake up.

---

#### 14.4.7.6 Interrupt Controller Basic Programming Model for Power On of IVA2.2 Subsystem

Noncombined events can be lost after power on wakeup of the DSP megamodule module. To avoid this, one solution is to replay the DSP CPU interrupt after restoring the interrupt selector and event combiner context.

- Programming model at boot time

There is no specific software setting needed to use combined/noncombined events during normal operation. However, at boot time, the event can be captured in the event-combiner event flag and not propagated to DSP. For this purpose, the following sequence must be performed:

1. The IVA2.2 logic ensures that interrupts are only presented to DSP megamodule after:
  - (a) The DSP megamodule module has its clock.
  - (b) The DSP megamodule module is correctly reset.

---

**NOTE:** Steps a and b ensure that the DSP megamodule module cannot miss a dropped event.

---

2. From the time the pre-idle sequence is started to the time when the IVA2.2 context is fully restored and operational after wakeup, it is assumed that only external (from device peripherals) interrupts can occur. DSP megamodule internal interrupts can result only from an application software side-effect; the application is stopped when entering the pre-idle sequence and is restarted only after IVA2.2 context is fully restored and operational (with special attention to memory protection). EDMA interrupts are inactive at this stage, as the EDMA module is completely reset after power up, and a software action is required to make the EDMA interrupts active again.
3. All device peripheral interrupts are level and are kept asserted until the software acknowledges the interrupt by writing 1 to the interrupt status register (DSP CPU ISR) bit corresponding to the enabled asserted event(s). The device peripheral must keep an event flag to track missed interrupts. For a complete description of the DSP CPU ISR register, see the C64x+ documentation ([Section 14.3.1.8](#)).
4. There is no specific requirement to configure or restore interrupt mapping, except having the interrupts globally disabled during the sequence:
  - (a) Set the DSP CPU TSR[0] or CSR[0] GIE bit to 0 to disable all interrupts except the reset interrupt and NMI (nonmaskable interrupt). The GIE bit is the same physical bit in the TSR and CSR registers. For a complete description of these registers, see the C64x + documentation ([Section 14.3.1.8](#)).
  - (b) Remap interrupts by configuring the IVA\_IC.INTMUX<sub>j</sub> registers (where j = {1 to 3}).
  - (c) Set the DSP CPU TSR[0] or CSR[0] GIE bit to 1 to enable all DSP CPU interrupts.

The DSP CPU software recognizes which degree of power state the C64x reaches when executing the IDLE instruction, because the PRCM module is under C64x software control. Therefore, the DSP CPU software can correctly skip some unnecessary parts of the pre-idle routines.

- State after reset for DSP CPU and IVA2.2 IC registers:
  - The DSP CPU IER register value is 0x0.
  - The DSP CPU IFR register value is 0x0 because the interrupt selector default mapping is routing only emulation and unmapped events.
  - The IVA\_IC.INTMUX<sub>j</sub> registers (where j = {1 to 3}): The default mapping is to route EVT<sub>x</sub> (with x = {0 to 3}) on INT<sub>y</sub> (with y = {4 .. 15}), that is, emulation and nonmapped events.
  - The IVA\_IC.EVTMASK<sub>i</sub> registers (where i = {0 to 3}) value is 0x0 (all events are unmasked). These registers values are don't care values because of the default interrupt selector mapping (where IVA\_IC.INTMUX<sub>j</sub> registers where j = {1 to 3}).
  - The IVA\_IC.EVTFLAG<sub>i</sub> registers (where i = {0, 1, 2, 3}): These registers log the possible wake-up interrupt(s) (if more than one). At this stage, a new wake-up interrupt from device peripherals cannot be missed, because interrupts are level in the device, waiting for a software acknowledge (the user must clear the interrupt in the module to deassert the interrupt line).

For a complete description of the DSP CPU IER and IFR registers, see the C64x+ documentation ([Section 14.3.1.8](#)).

- State after reset for WUGEN registers: two cases depending on the reset type:

- In case of cold power-on reset (the CORE power domain was in OFF state), the IVA\_WUGEN.WUGEN\_MEVT0 register value is 0xFFFFFFFF and the IVA\_WUGEN.WUGEN\_MEVT1 register value is 0xFFFF, meaning that all interrupts are masked.
- In case of warm power-on reset (the CORE power domain was in ACTIVE state), the WUGEN\_MEVT0 and WUGEN\_MEVT1 registers value is the previous programmed one, enabling only wake-up interrupts.
- Programming model for a correct warm-reset:

The software user must replay the noncombined events required for wakeup (if any):

1. Globally mask interrupts by setting the DSP CPU TSR[0] or CSR[0] GIE bit to 0 (already done at boot time).
2. Restore the interrupt selector configuration:
  - (a) IVA\_IC.INTMUXj register (where j = {1 to 3})
  - (b) IVA\_IC.EVTMASKi register (optional, where i = {0 to 3})
  - (c) IVA\_IC.INTDMASK register (optional)
3. Replay the noncombined event captured in IVA\_IC.EVTFLAGi (where i = {0 to 3}):
 

For each DSP CPU interrupt I = (4 to 15)

```
{
(a) Grab mapped event by setting the IVA_IC.INTMUXj INTSELi[6:0] field (where j = {1 to 3}).
(b) Check if the event is combined (EVT0...3) or not combined (EVT4...127).
(c) If combined, exit the loop and go to next loop iteration.
(d) If noncombined:
    (i) Check whether the event is pending in the IVA_IC.EVTFLAGi EFy bit (where i = {0 to 3} and y = {0 to 127}).
    (ii) If not pending, exit the loop and go to the next loop iteration.
    (iii) If pending, set the associated IFi bit in the DSP CPU IFR register.
}
```

---

**NOTE:** Software must ensure that an event is enabled only once in the DSP megamodule interrupt selector/combiner: If a noncombined event is mapped to an enabled DSP CPU interrupt, the associated combined event is masked in the associated IVA\_IC.EVTMASKi (where i = {0 to 3}) register (and/or the combined event is not mapped to the DSP CPU interrupt). Reciprocally, if a combined event is mapped to a DSP CPU interrupt, all the unmasked events in the associated IVA\_IC.EVTMASKi (with i = {0, 1 to 3}) register are not mapped as noncombined events to an enabled DSP CPU interrupt (through the DSP CPU IER register).

---

Software program example for Step 3:

```
/* ----- */
/* Replays IFR bits associated to noncombined events */
/* Assumes interrupts globally disabled (GIE bit set to 0)*/
/* Assumes IVA_IC.INTMUXj() and IVA_IC.EVTFLAGi() are access macros to DSP megamodule IC registers */
/* ----- */
myIPR = IPR; // save IPR
for(I=0; i<12; I++) { // for each CPU maskable interrupt
myEvt = ( INTMUX( I >> 2 + 1 ) >> ( ( I & 0x3 ) << 3 ) ) & 0x7F;
if(myEvt >= 4) { // noncombined event
if( (EVTFLAG(myEvt >> 5) >> (myEvt & 0x1F) ) & 0x1 ) {
myIPR |= (1<<(I+4));
}
}
}
```

```

}
IPR=myIPR; // update IPR register
/* ----- */
/* Interrupts can be globally re-enabled from that point*/
/* ----- */

```

4. Restore the CPU interrupt configuration by setting the DSP CPU IER register accordingly.
5. Restore the IVA2.2 context (except saved return-PC).
6. Globally enable the interrupts by setting the DSP CPU TSR[0] or CSR[0] GIE bit to 1.
7. Branch to saved return-PC.

For a complete description of the DSP CPU TSR, CSR, IER, or IFR registers, see the C64x+ documentation ([Section 14.3.1.8](#)).

- Procedure for a correct cold reset
  1. Globally mask interrupts by setting the DSP CPU TSR[0] or CSR[0] GIE bit to 0 (already done at boot time).
  2. Restore the interrupt selector configuration:
    - (a) IVA\_IC.INTMUX<sub>j</sub> register (where j = {1 to 3})
    - (b) IVA\_IC.EVTMASK<sub>i</sub> register (optional, with i = {0 to 3})
    - (c) IVA\_IC.INTDMASK register (optional)
  3. It is unnecessary to replay events, because they are masked in [WUGEN\\_MEVT0](#) and [WUGEN\\_MEVT1](#) registers (default WUGEN module configuration). This can be done to simplify the boot sequence without discriminating between cold and warm reset.
  4. Restore the CPU interrupt configuration by setting the DSP CPU IER REGISTER accordingly.
  5. Restore the WUGEN module context. This can be forced even in warm reset to simplify the boot sequence without discriminating between cold and warm reset.

---

**NOTE:** If Steps 3 and 5 are performed systematically, the boot code can be shared between warm and cold reset boot without programming two distinct software boot codes.

---

6. Restore the rest of the IVA2.2 subsystem context (except saved return-PC).
7. Globally enable the interrupts by setting the DSP CPU TSR[0] or CSR[0] GIE bit to 1.
8. Branch to saved return-PC.

#### 14.4.7.7 Video and Sequencer Module interrupt Handling

##### 14.4.7.7.1 Sequencer Interrupt

The sequencer uses a single FIQ interrupt. This single interrupt is driven by all the video accelerator interrupts, DSP EDMA interrupts, DSP megamodule soft interrupts, and error interrupts. Registers are available to manage these interrupts in the sequencer.

Before servicing an interrupt, the sequencer ISR must:

1. Identify the source event(s) for the interrupt line assertion
2. For each source event:
  - (a) Clear the interrupt at the source (in the module interrupt clear register)
  - (b) Clear the interrupt at the second-level (sequencer) interrupt controller
  - (c) Service the interrupt event

For more information about sequencer interrupts, see [Table 14-6](#).

## 14.4.8 Memory Management

### 14.4.8.1 External Memory

#### 14.4.8.1.1 Cacheability

The L1P, L1D, and L2 cache sizes are all 0K byte after reset.

- The user enables the L2 cache by writing 0x2 (maximum cache is 64K bytes) to the IVA\_XMC.L2CFG register.
- However, this is not sufficient, because the region external to the IVA2.2 is configured as a noncached area after reset. The user must configure the external area to be cached by setting the IVA\_XMC.MAR<sub>i</sub>[0] PC bit to 1, *i* referring to the index of the related 16-MB page (starting from *i* = 16 for the first external page at address 0x1000 0000).

The MAR settings only control the L2 and L1D cache's response to CPU data and program fetches. L1P caches the memory range regardless of the values of the MAR bits.

#### 14.4.8.1.2 Virtual Addressing

The device embeds two instances of MMU: one instance is camera MMU (also named MMU1) dedicated to the camera subsystem; the other instance is IVA2.2 MMU (also named MMU2) used by the IVA2.2 subsystem. For more information about MMU2 software settings at IVA2.2 boot, see [Section 14.4.1.2, Example of IVA2.2 Boot](#).

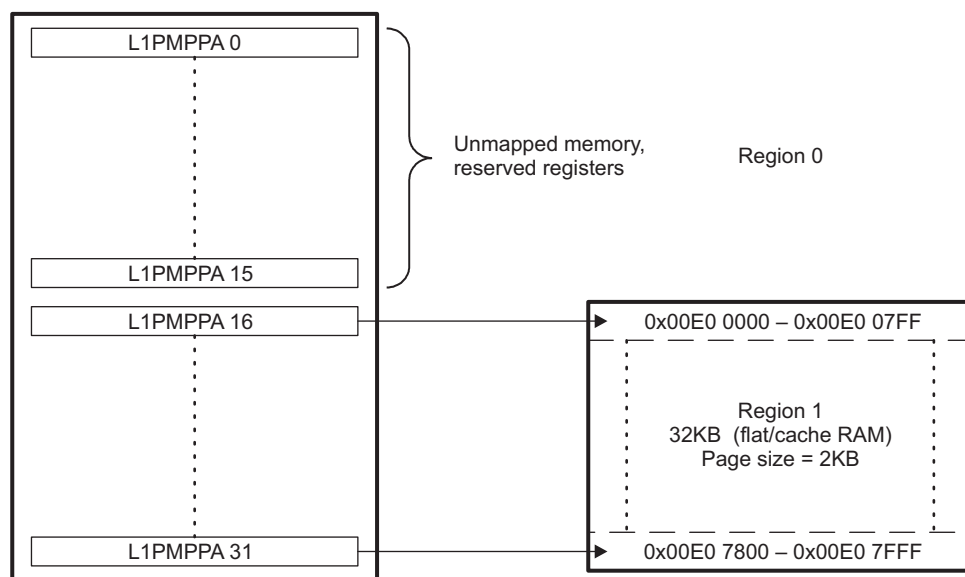

For a complete programming guide of IVA2.2 MMU, see [Chapter 8, Memory Management Units](#).

### 14.4.8.2 Internal Memory

#### 14.4.8.2.1 Memory Protection

The DSP megacell memory protection divides the memory map into pages and defines a per-page permission structure. This permission structure is in the MPPA registers: IVA\_XMC.L1PMPPA<sub>k</sub>, IVA\_XMC.L1DMPPA<sub>k</sub>, IVA\_XMC.L2MPPA<sub>j</sub> for L1P, L1D, L2 memory protection, and TPCC\_MPPA<sub>g</sub>, TPCC\_MPPA<sub>j</sub> for EDMA memory protection. [Figure 14-41](#), [Figure 14-42](#), and [Figure 14-43](#) show which register corresponds to each page permission structure.

Figure 14-41. L1P Memory Protection Registers

iva22-042

Figure 14-42. L1D Memory Protection Registers

iva22-043

Figure 14-43. L2 Memory Protection Registers

iva22-044

**NOTE:** When memory is used as cache, all its corresponding MPPA registers should be set to 0x0000.

Table 14-96 shows which register corresponds to each memory address for megacell internal memory.

Table 14-96. IVA2.2 Megamodule Memory Protection Page Registers

63	-	-	0x007F F000 - 0x007F FFFF

All these registers include three permission fields in a 16-bit permission entry in the memory protection page attribute MPPA register:

- Allowed ID field:

Each requestor on the device has an N-bit code associated where it that identifies it for privilege purposes. This code, referred to as the VBUS PrivID, accompanies all memory accesses and DMAs/IDMAs on behalf of that requestor. That is, when a requestor triggers a DMA/IDMA transfer directly, either by writing to IDMA registers or by triggering the execution of a set of EDMA parameters, the corresponding DMA engine captures the PrivID of the requestor and provides that PrivID with the transfer.

Each memory protection entry is associated with an 8-bit allowed-IDs field that indicates which requestors can access the given page. The memory protection hardware maps the PrivIDs of all possible requestors to bits in the allowed-IDs field in the memory protection entries. The allowed-IDs field discriminates among the various CPUs, non-CPU requestors, and the accesses of a given CPU to its own local memories:

- AID0 through AID5 map small-numbered VBUS PrivIDs to allowed ID bits.
- An additional allowed-ID bit, AIDX, captures accesses by higher-numbered PrivIDs.
- The LOCAL bit treats CPU accesses to its local L1s and L2 specially. Only the L1 and L2 memory

controllers implement the LOCAL bit.

When set to 1, the AID bit grants access to the corresponding PrivID. When set to 0, the AID bit denies access to the corresponding requestor.

PrivID assignments for bits AID0 through AIDX apply to:

- CPU memory and IDMA memory: IVA\_XMC.L1PMPPAk[15:9] for L1P memory, IVA\_XMC.L1DMPPAk[15:9] for L1D memory, and IVA\_XMC.L2MPPAj[15:9] for L2 memory
- EDMA memory: TPCC\_MPPAG[15:9] and TPCC\_MPPAj[15:9] for EDMA block

The AIDX bit maps to PrivIDs that do not have dedicated AID bits associated with them. This bit refers to external mastering peripherals, especially on devices with a large number of CPUs. If a given device must discriminate among external mastering peripherals, it can assign lower-numbered PrivIDs to these peripherals.

For the EDMA module, the AIDX bit is the TPCC\_MPPAj[9] and TPCC\_MPPAj[9] EXT bits.

The LOCAL bit governs DSP CPU accesses to its own local L1 and L2 memories. It is defined in IVA\_XMC.L1PMPPAk[8] for L1P memory, in IVA\_XMC.L1DMPPAk[8] for L1D memory, and in IVA\_XMC.L2MPPAj[8] for L2 memory. It is not defined for EDMA.

With respect to the allowed ID field, the DSP megamodule treats all remote CPU accesses to DSP megamodule memories identically to DMA accesses from that remote CPU. Therefore, DSP megamodule uses the PrivID to consult the corresponding AID bit when considering remote accesses.

However, the DPS megamodule module never compares local accesses to L1 and L2 memory against the AID bits in the allowed ID field. Instead, it consults the LOCAL bit to determine whether the CPU can access its local memory.

With this scheme, a software program can designate a page as direct CPU access only by setting the LOCAL bit to 1 and setting all other allowed IDs to 0. Conversely, a software program can designate a page as DMAs issued from this CPU only by setting its AID bit and clearing the LOCAL bit. Such a setting is limited, but it can be useful in a sensitive environment, or in the context of a device driver.

- Request-Type Based Permissions field:

The DPS megamodule memory protection model defines three fundamental functional access types: read, write, and execute. Read and write refer to data accesses originating through the load/store units on the DSP CPU or through the DMA/IDMA engines. Execute refers to accesses associated with program fetch.

The DSP megamodule memory protection model allows control of read, write, and execute permissions independently for both user and supervisor mode. This results in the 6-bit permission field shown in [Table 14-97](#).

**Table 14-97. Request-Type Access Controls**

Bit Name	Description
SR	Supervisor can read
SW	Supervisor can write
SX	Supervisor can execute <sup>(1)</sup>
UR	User can read
UW	User can write
UX	User can execute <sup>(1)</sup>

<sup>(1)</sup> IVA\_XMC.L1DMPPAXX do not implement these bits.

For each bit, writing 1 permits the access type, and writing 0 denies it. For instance, setting the UX bit to 1 means that user mode can execute from the given page. The DSP megamodule allows specifying all six of these bits separately. For L1P, L1D, and L2 memories, and for EDMA, these bits are defined in IVA\_XMC.L1PMPPAk[5:0], IVA\_XMC.L1DMPPAk[5:0], IVA\_XMC.L2MPPAj[5:0], and TPCC\_MPPAG[5:0] and TPCC\_MPPAj[5:0], respectively.

**NOTE:** IVA\_XMC.L1DMPPAK do not implement the SX and UX bit, because execution is not possible from L1D memory. Therefore, these bits are reserved and should not be used in these registers.

- Other registers

The memory protection block records the address of the fault in the peripheral memory protection fault address register (MPFAR). It records the rest of the information about the fault in the peripheral memory protection fault status register (MPFSR); this register is formatted similarly to the MPPA. Software can write to the memory protection fault command register (MPFCR).

The MPFAR corresponds to the following registers: IVA\_XMC.L1PMPFAR for L1P memory, IVA\_XMC.L1DMPFAR for L1D memory, IVA\_XMC.L2MPFAR for L2 memory, IVA\_IDMA.ICFGMPFAR for IDMA, and TPCC\_MPFAR for EDMA.

The MPFSR corresponds to the following registers: IVA\_XMC.L1PMPFSR for L1P memory, IVA\_XMC.L1DMPFSR for L1D memory, IVA\_XMC.L2MPFSR for L2 memory, IVA\_IDMA.ICFGMPFSR for IDMA, and TPCC\_MPFASR for EDMA.

Using the MPFSR register, a memory protection fault can be decoded as follows by software:

- If the LOCAL status bit is set to 1, the request was a local DSP CPU request to its own memories. Otherwise (if the LOCAL status bit is set to 0), the VBUS ID of the faulting requestor is in the MPFSR[15:9] field.
- The value of the access type field (SR, SW, SX, UR, UW, UX) indicates the type of access that was at fault.

The MPFAR and MPFSR store information for only one fault. The hardware block holds the fault information until the software clears it by writing to MPFCR.

The user clears the recorded fault by setting the MPFCR[0] MPFCLR bit to 1. Writing 1 to this bit clears both MPFAR and MPFSR registers. The MPFAR and MPFSR read-only registers do not respond to writes. Once the user clears the fault, the hardware records the next protection violation, and signals an exception when it occurs. Writing 1 to any other bit of the MPFCR has no effect on the memory protection registers. Writing 0 to the MPFCR[0] MPFCLR bit also has no effect.

The MPFCR corresponds to the following registers: IVA\_XMC.L1PMPFCR for L1P memory, IVA\_XMC.L1DMPFCR for L1D memory, IVA\_XMC.L2MPFCR for L2 memory, IVA\_IDMA.ICFGMPFCR for IDMA, and TPCC\_MPFASR for EDMA.

- Events generated to DSP megamodule IC block

Internal events are generated to inform the DSP megamodule module for memory protection:

- CCMPINT (EVT28) is generated for a TPCC memory protection interrupt.
- SYS\_CMPA (EVT 119) is generated in case of a SYS CPU memory protection fault.
- PMC\_CMPA (EVT120) and PMC\_DMPA (EVT121) are generated in case of CPU and DMA memory protection faults, respectively, on PMC.
- DMC\_CMPA (EVT122) and DMC\_DMPA (EVT123) are generated in case of CPU and DMA memory protection faults, respectively, on DMC.
- UMC\_CMPA (EVT124) and UMC\_DMPA (EVT125) are generated in case of CPU and DMA memory protection faults, respectively, on UMC.
- PMC\_CMPA (EVT126) is generated in case of a CPU memory protection fault on EMC.

The AID of the DSP appears in the DNUM control register in the CPU. DNUM is the DSP core number register; it is used to identify which DSP subsystem accessed the shared resources. Because there is only one C64x+:

- GEM\_DNUM[7:4] always equals 0x0.
- GEM\_DNUM[3:0] equals 0x0 because DSP is labeled as CPU0 in the single core system.

Thus, the possible requestors are:

- C64x
- IDMA
- EDMA

- Any device L3 initiator (through the IVA2.2 slave port)

The PrivID (relative to the DNUM register) equals 0. The ID of IVA DMA accesses is always 0x0, because the IVA DMA inherits ID from DSP megamodule. All accesses on the IVA2 slave port to local memories are seen by DSP megamodule as accesses from an external (non-DSP megamodule) initiator.

Thus, the hard-mapped memory protection IDs are:

- AID0, used for IVA DMA
- AID1 to AID5 (not used)
- AIDX, used by the slave port (L3 initiators)
- LOCAL bit, used by DSP loads, stores, and program fetches to memory attached directly to DSP megamodule

#### 14.4.8.2.2 Bandwidth Management

The bandwidth management scheme can be summarized as weighted-priority-driven bandwidth allocation. Each requestor (EDMA, IDMA, CPU, etc.) is assigned a priority level on a per-transfer basis. The programmable priority level has a single meaning throughout the system: there is a total of nine priority levels, where priority 0 is highest and priority 8 is lowest priority. When requests for a single resource contend, access is granted to the highest priority requestor. When contention occurs for multiple successive cycles, a contention counter ensures that the lower priority requestor gets access to the resource every one out of  $n$  arbitration cycles, where  $n$  is programmable through the MAXWAIT field. For each identified requestor, a corresponding MAXWAIT field controls the maximum number of cycles that a request can be blocked.

- CPUARB registers: CPU priority and MAXWAIT programming model

The DSP CPU-initiated transfers consist of two components:

1. Program fetch transfers are issued by the CPU to the PMC, and the resulting L1P cache coherency operations (such as alloc/evict) are then issued to the UMC.
2. Data load/store transfers are issued by the CPU to the DMC, and the resulting L1D cache coherency operations (such as alloc/evict/long distance accesses) are then issued to the UMC.

Both program and data requests use the CPUARB values to define the maximum wait time (CPUARB[5:0] MAXWAIT) and priority (CPUARB[18:16] PRI). The effect of the CPUARB values is not just local to PMC or DMC. Priority/maxwait time applies to DMC/PMC cache transactions throughout the DSP megamodule and controls arbitration at each relevant subblock within DSP megamodule. The priority (PRI) and MAXWAIT field is programmed locally in the UMC, DMC, and EMC blocks, through the IVA\_UMC.CPUARBU, IVA\_DMC.CPUARBD, and IVA\_IDMA.CPUARBE PRI and MAXWAIT fields, respectively.

The default value of the CPUARB[18:16] PRI field is set so that CPU transactions are second to highest in the system. This should be a relatively typical value used in most systems, which results in the DSP CPU being granted highest priority most of the time, but a McBSP-type peripheral (typically programmed as the highest priority transfer for sDMA requests) can interrupt the DSP CPU transfers on a nearly immediate basis.

---

**NOTE:** CPU priority is software-programmable, but it is considered static (1-time-programmable) for bandwidth management. That is, during normal operation, all DSP CPU transactions are of the same priority. There is no concept of priority inheritance for CPU-initiated transfers as a result of CPU transfer A set at priority X and CPU transfer B set at priority Y. Because CPUARB must be programmed by the CPU, and is therefore a run-time programming, the effect of the new CPUARB value must take effect for future CPU transfers.

---

- UCARB registers - User coherence operations

User coherence operations are broken into two types, block-oriented coherence and global coherence operations. The priority of these requests relative to other requests in the system varies as follows:

- Global user coherence: Always highest priority
- Block-oriented coherence: Always lowest priority

Because user coherence priority is fixed, the UCARB registers do not include a priority field. And because global user coherence operations are inherently highest priority, the MAXWAIT field programming applies only to block-oriented user coherence operations, not to global cache operations.

The UCARB[5:0] MAXWAIT field affects only the UMC (IVA\_UMC.UCARBU register) and the DMC (IVA\_DMC.UCARBD register). The priority values (being fixed) are assumed to be known at both the UMC and the DMC.

---

**NOTE:** The UCARB[5:0] MAXWAIT field (and the implied priorities) does not control the priority of coherence operations that result from DMA transactions or CPU transactions.

---

- IDMAARB registers - IDMA priority programming model

IDMA supports two active transfers at any time through IDMA channel 0 (used for memory to/from configuration bus transfers) and IDMA channel 1 (used for memory-to-memory transfers). The IDMAARB[5:0]MAXWAIT field is used to determine the maximum wait time for IDMA transactions. The priority level is not programmed through the IDMAARB register. Instead, the priority level is programmed directly through the IDMA control registers. In summary, IDMA transfer priority is:

- IDMA channel 0: Always highest priority
- IDMA channel 1: Programmable priority: the IVA\_IDMA.IDMA1\_COUNT[31:29] PRI field

For this reason, the IDMAARB registers do not include a priority field. The IDMAARB[5:0] MAXWAIT field affects not only the EMC (IVA\_IDMA.IDMAARBE register) but also the UMC (IVA\_UMC.IDMAARBU register) and the DMC (IVA\_DMC.IDMAARBD register).

---

**NOTE:** IDMA channel 0 has no need for priority inheritance, because it is always the highest priority transfer in the system.

However, if an IDMA channel 1 transfer and an IDMA channel 0 transfer are pending at the same instant, but the IDMA channel 1 queue is blocked because of contention with another requestor, the IDMA channel 1 transfer should briefly inherit the priority of the IDMA channel 0 transfer (which is always 0x0) so that the pending dataphase on IDMA channel 1 can complete and the normal priority mechanism can take control.

---

- SDMAARB registers - Slave DMA priority programming model

The DSP megamodule slave DMA (SDMA) interface can support multiple active transfers at a time. The SDMAARB[5:0] MAXWAIT field controls the maximum wait time for all slave DMA transactions. The priority level is not programmed by the SDMAARB register. Instead, the priority level is dictated by the priority fields of the IVA\_TPCC.QUEPRI register.

The SDMAARB[5:0] MAXWAIT field does not affect only the EMC (IVA\_IDMA.SDMAARBE register), but also the UMC (IVA\_UMC.SDMAARBU register) and the DMC (IVA\_DMC.SDMAARBD register).

---

**NOTE:** Because of the pipelined nature of the VBUS interface, the DSP megamodule module can have multiple DMA transfers in flight at a time. To avoid priority inversion, the DSP megamodule must not only evaluate the priority of the transfer at the head of the EMC queue(s), but the priority of all transfers that have been accepted/queued on the VBUS interface(s), and of higher priority transfers that are queued in the device-level DMA infrastructure.

---

- MDMAARBE register - Master DMA priority programming model

The IVA\_IDMA.MDMAARBE[18:16] PRI field controls the submission priority for master DMA transactions (which are a result of cache misses or long-distance accesses to nonconfiguration space) and configuration bus transactions (long-distance accesses to configuration space or IDMA transfers to configuration space).

The IVA\_IDMA.MDMAARBE priority is different from other programmable priorities in the system, in that the priority value does not affect internal arbitration for resources. This PRI[3:0] value is simply used as the VBUS priority value for all transactions initiated by the DMA master interface or memory-mapped register configuration interface.

Arbitration for the internal half of the transfer depends on the initiator (which could be DSP CPU, PMC, or DMC) or user coherence (UMC), or IDMA, etc. Arbitration for the external half of the transfer is DMA-dependent, and should rely on the Vbus priority, which is copied from the IVA\_IDMA.MDMAARBE[18:16] PRI field.

---

**NOTE:** Because no internal arbitration results from the IVA\_IDMA.MDMAARBE register, there is no need for the MAXWAIT field in this register.

---

### 14.4.8.3 SL2 Memory Management

#### 14.4.8.3.1 SL2 Performance Optimizations

To limit the number of accesses through the SL2 interface and to optimize bandwidth, it is recommended that the user access SL2 using, as much as possible, bursts and aligned on burst boundaries. Optimum bandwidth savings can be obtained by doing bursts of 8x32 aligned on 32-byte boundaries.

This can be done using ARM968 (sequencer module) LDM or STM instructions. For details, see the ARM reference manual.

#### 14.4.8.3.2 SL2 Performance Limitations

Accesses through the SL2IF OCP interface to SL2 memory are not intended to be optimized for single reads, but only for bursts. Maximum bandwidth can be obtained using bursts of 8x32b bursts or larger (bursts larger than 8x32 are divided into 8x32 bursts). Generating single requests to the SL2IF interface has two disadvantages:

- Uses a large portion of the SL2 bandwidth, resulting in iME and iLF performance degradation
- Increases dynamic power consumption

In particular, ARM968 instruction fetches generate single requests on the local interconnect. SL2 is not optimized for ARM968 instruction direct fetching. If the ITCM is too small for an ARM968 program, an ARM968 program must be DMAed in from memory (possibly SL2, as DMA accesses are bursted).

#### 14.4.8.3.3 SL2 Illegal Accesses

It is illegal for the user to generate unaligned bursts that span SL2 address range boundaries.

## 14.4.9 IVA2.2 Power Management

### 14.4.9.1 Clock Management

#### 14.4.9.1.1 Clock Configuration

The IVA2.2 subsystem receives one single-clock signal from the PRCM, the DPLL2\_ALWON.FCLK.

From the DPLL2\_ALWON.FCLK functional clock provided by the PRCM, three internal clocks (CD0\_CLK, CD1\_CLK, and CD2\_CLK) are generated by the IVA2.2 DPLL and SYSC modules:

- The frequency of the CD0\_CLK clock can be software-tuned with a PRCM register by setting the PRCM.CM\_CLKSEL1\_PLL\_IVA2 and PRCM.CM\_CLKSEL2\_PLL\_IVA2 registers.
- The CD1\_CLK clock is always a divide-by-two of the CD0\_CLK clock and its frequency cannot be changed by software.
- The CD2\_CLK clock is always a divide-by-two of the CD0\_CLK clock and its frequency cannot be changed by software.

For a complete description of the PRCM registers discussed in this section, see [Chapter 4, Power, Reset, and Clock Management](#).

#### 14.4.9.1.2 Clock Gating

- IVA2.2 subsystem

The IVA2.2 internal clocks can be hardware-disabled by the PRCM when the MSTANDBY/WAIT handshake protocol occurs. To configure the PRCM so that IVA2.2 internal clocks are hardware-supervised, set the PRCM.CM\_AUTOIDLE\_PLL\_IVA2[2:0] AUTO\_IVA2\_DPLL field to 0x1.

When the IVA2.2 subsystem does not require its internal clocks, they can be disabled at the PRCM level by setting the PRCM.CM\_FCLKEN\_IVA2[0] EN\_IVA2 bit to 0.

For a complete description of these PRCM registers, see [Chapter 4, Power, Reset, and Clock Management](#).

- SYSC module

The IVA2.2 SYSC module implements automatic clock gating on internal hardware detection of the absence of activity. The transition from clock-gated to clock-nongated state is operated with no cycle latency penalty.

The automatic clock-gating feature is enabled by setting the IVA\_SYSC.SYSC\_SYSCONFIG[0] AUTOIDLE bit to 1 (default value). This feature can be disabled by setting the IVA\_SYSC.SYSC\_SYSCONFIG[0] AUTOIDLE bit to 0 and making the clock free-running.

- WUGEN module

The IVA2.2 WUGEN module implements automatic clock gating on internal hardware detection of the absence of activity. The transition from clock-gated to clock-nongated state operates with no cycle latency penalty.

Automatic clock gating is enabled by setting the IVA\_WUGEN.WUGEN\_SYSCONFIG[0] AUTOIDLE bit to 1 (default mode). The clock can be made free-running by setting the IVA\_WUGEN.WUGEN\_SYSCONFIG[0] AUTOIDLE bit to 0.

- TPCC from EDMA module

The EDMA (or TPCC) module implements automatic clock gating on internal hardware detection of the absence of activity. The transition from clock-nongated to clock-gated state operates with no cycle latency penalty.

### 14.4.9.2 Reset Management

In addition to hardware reset signals generated by the PRCM, the IVA2.2 subsystem can be reset by software control.

The three DSP power domain software resets (DSP\_RST1, DSP\_RST2, and DSP\_RST3) are partial warm-reset sources. These software resets map to the PRCM.RM\_RSTCTL\_IVA2[0] RST1\_IVA2 bit, the RM\_RSTCTRL\_IVA2[1] RST2\_IVA2 bit, and the PRCM.RM\_RSTCTL\_IVA2[2] RST3\_IVA2 bit, respectively, in the PRCM register RM\_RSTCTRL\_IVA2.

Setting these 3 bits to 1 performs a software reset to the IVA2.2 subsystem.

The reset status is logged in the PRCM.RM\_RSTST\_IVA2[8] IVA2\_SW\_RST1 read-only bit for IVA2\_RST1 software reset, the PRCM.RM\_RSTST\_IVA2[9] IVA2\_SW\_RST2 read-only bit for IVA2\_RST2 software reset, and the PRCM.RM\_RSTST\_IVA2[10] IVA2\_SW\_RST3 read-only bit for IVA2\_RST3 software reset.

For a complete description of these PRCM registers, see [Chapter 4, Power, Reset, and Clock Management](#).

---

**NOTE:** Software reset can be applied only while the IVA2.2 subsystem is in clock-off mode.

---

#### 14.4.9.3 Power-Down and Wake-Up Management

- DSP megamodule power-down controller (PDC)

The DSP megamodule embeds a PDC block that allows power-down management by software.

Individual DSP megamodule blocks such as DSP CPU, PMC, DMC, EMC, and UMC can be powered off by the PDC.

- This software control is ensured by the IVA\_SYS.PDCCMD register:
  - By setting the IVA\_SYS.PDCCMD[16] GEMPD bit to 1, the user enables power-down management during idle mode.
  - By setting the IVA\_SYS.PDCCMD xMCLOG[1:0] and IVA\_SYS.PDCCMD xMCMEM[1:0] fields (x = {P, D, U}), the user controls the XMC clock-gating and standby memory modes. For example, DMC is controlled with the IVA\_SYS.PDCCMD[5:4] DMCLG and IVA\_SYS.PDCCMD[7:6] xMCMEM fields.
  - The programming sequence for transition to clock-off state is as follows:

Before executing the IDLE instruction, the user must perform the following sequence:

1. Write 1 to the IVA\_SYS.PDCCMD[16] GEMPD bit (standby state); by default, the IVA\_SYS.PDCCMD xMCLOG[1:0] and IVA\_SYS.PDCCMD xMCMEM[1:0] (x = {P, D, U}) field values are all 0x1, so that module clock gating is enabled and standby mode of memories is statically activated after the IDLE instruction executes.
2. Mask all interrupts not intended to wake up the IVA2.2 subsystem.
3. Program the PRCM so that IVA2.2 clocks are cut on IVA2.2 standby. For more information, see [Chapter 4, Power, Reset, and Clock Management](#).
4. Read back all the written registers to ensure write completion.

The user must also ensure that no other instruction is executed parallel to the IDLE instruction.

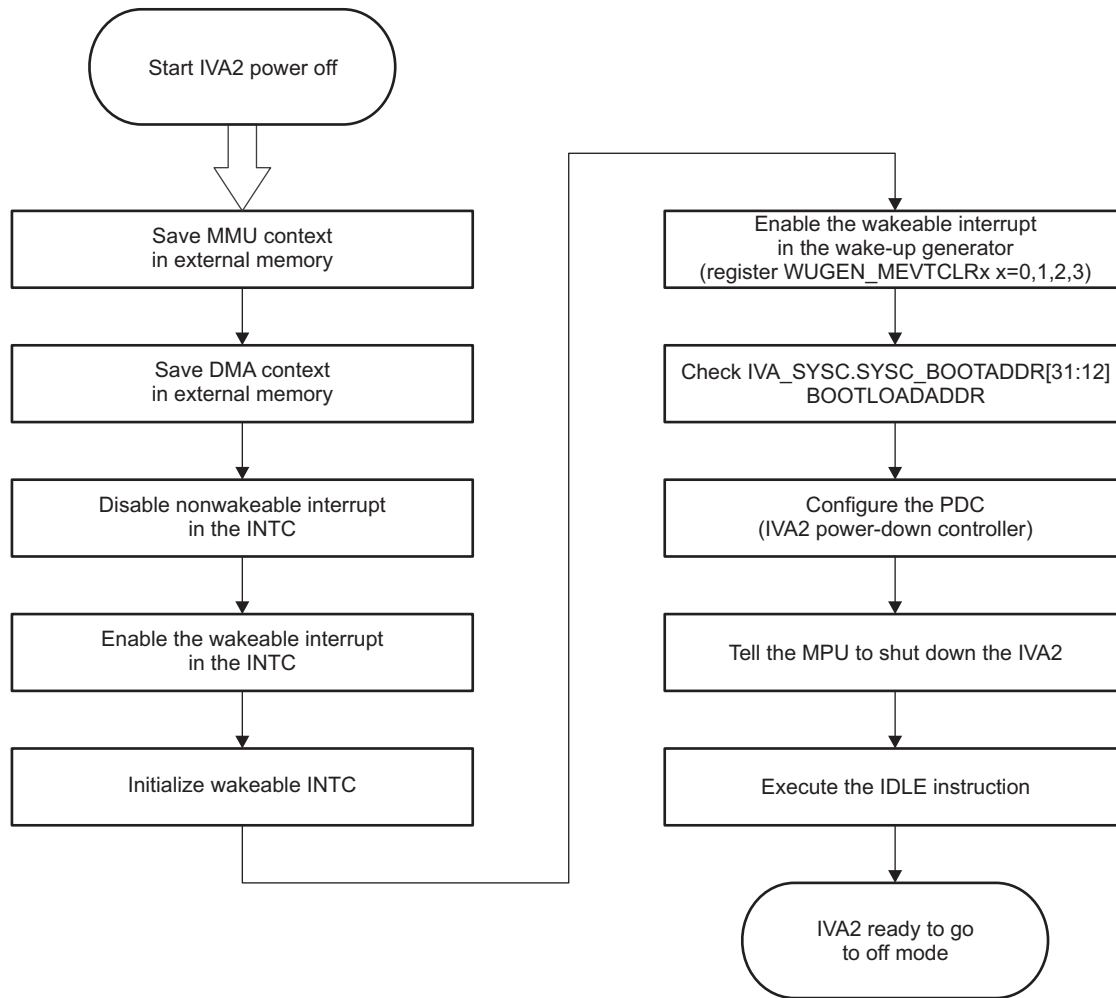

When a clock stop request is asserted, the PDC\_INT event (EVT118, see [Table 14-3](#)) is generated to the DSP megamodule IC module to inform the DSP CPU to initiate a power-down sequence. For more information about interrupt management, see [Section 14.4.7, Interrupt Management](#).

- Programming sequence for transition to power-off state:

Before executing the IDLE instruction, the user must perform the sequence shown in [Figure 14-44](#).

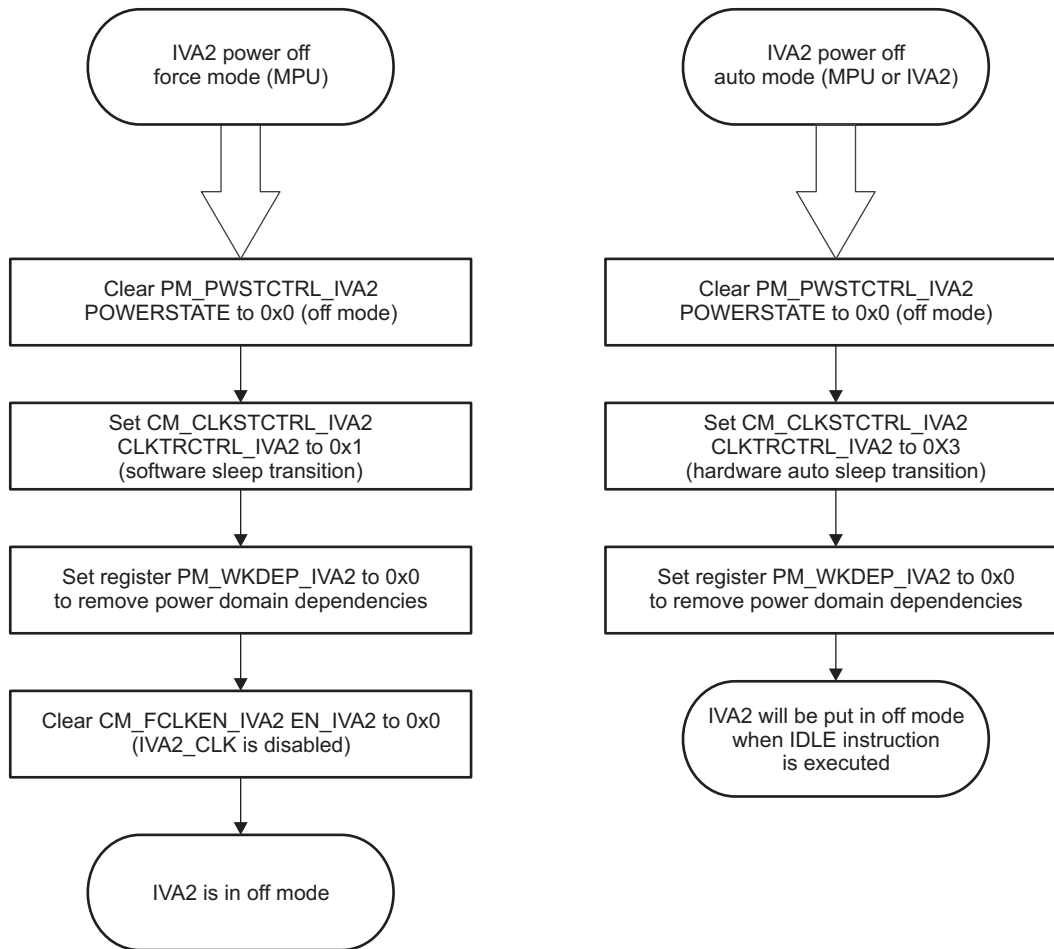

Figure 14-44. IVA2 Power Off

iva22-045

The user must also ensure that no other instruction is executed parallel to the IDLE instruction. When IVA2 is ready to go to off mode, there are two ways to completely shut down IVA2 subsystem (see [Figure 14-45](#)):

Figure 14-45. IVA2 Power Down

iva22-046

**CAUTION**

The IVA2 clock must not be stopped manually; otherwise, the WUGEN module inside the IVA2 has no functional clock and cannot wake up the IVA subsystem.

When the IVA2 is shut down, it can be waked up by an external event. The boot code executed after wakeup must include at least the following steps (see [Figure 14-46](#)):

**Figure 14-46. IVA2 Wake Up**

iva22-047

#### 14.4.9.4 Powering Down L2\$ Memory While IVA2 is Active

If the L2\$ is unused while the DSP is active, the IVA2.2 can completely switch off the 96-KB SRAM attached to the L2\$ controller. This typically happens when the DSP is running at a low frequency (for instance, at the same frequency as the SDRAM) where L2\$ is not justified. The alternative is to switch off L2\$ SRAM completely, losing all L2-cache content and memory-mapped SRAM (from 0x10800000 to 0x1080FFFF). It is impossible to put the SRAM in low-leakage mode and retain data/program while the DSP is active. Also, L2 cache SRAM is the only memory/cache that supports this off mode while DSP is active. L1D and L1P cache SRAM off modes are not supported while DSP is active.

The sequence to enter L2\$ off mode while DSP is active follows:

1. Save [L2CFG](#) and disable the L2\$ by converting L2-cache SRAM to memory-mapped SRAM only (96KB): `L2CFG.L2MODE = 0x0`.
2. Read back [L2CFG](#) to ensure that Step 1 is complete.
3. Save [L2MPPAj](#) ( $j = 0$  to 31) and write 0x0 to the [L2MPPAj](#) ( $j = 0$  to 31) registers to report access to L2 memory (for debug) and enable associated permission check interrupt and/or exception.
4. Configure the PRCM to switch off L2:  
`PRCM.PM_PWSTCTRL_IVA2.SHARED_L2_CACHE_FLAT_ON_STATE = 0x0`.
5. Read back `PRCM.PM_PWSTCTRL_IVA2` to ensure that Step 4 is complete.

After this sequence, the user must not access the L2 memory. If this happens (typically in code under debug), a memory-protection interrupt and/or exception is taken.

The sequence to exit L2\$ off mode (while DSP is active) follows:

1. Configure the PRCM to switch on L2:  
PRCM.PM\_PWSTCTRL\_IVA2.SHARED\_L2CACHEFLATONSTATE = 0x3.
2. Read back PRCM.PM\_PWSTCTRL\_IVA2 to ensure that Step 1 is complete.
3. Restore [L2MPPAj](#) (j = 0 to 31).
4. Restore [L2CFG](#).
5. Read back PRCM.PM\_PWSTCTRL\_IVA2 to ensure that Step 4 is complete.

---

**NOTE:** After this sequence, L2\$ is empty and content in L2\$-SRAM configured as memory-mapped is lost.

---

---

**NOTE:** This mode does not provide large power savings, but is provided in IVA2.2 as an enabler for power-management software development, anticipating that leakage is a major contributor to power consumption, even in active mode.

---

### 14.4.9.5 Video and Sequencer Module Management

#### 14.4.9.5.1 Module Dynamic Power Savings

The video accelerator/sequencer modules implement auto-clock gating to save dynamic power consumption when no activity is locally detected. For some modules (iME, iLF, sequencer, video system controller), it is also possible to disable auto-gating by software. Auto-clock gating has no performance impact.

To optimize local power management, configure the following registers (default values):

- IVA.iME\_SYSCONFIG Autoidle = 1
- IVA.iLF\_SYSCONFIG Autoidle = 1
- IVA.SEQ\_SYSCONFIG Autoidle = 1
- IVA.VIDEOSYSC\_SYSCONFIG Autoidle = 1

#### 14.4.9.5.2 System Dynamic Power Savings

For further system dynamic power savings, a module root clock can be independently stopped when the module has no activity.

The root clock of a module can be stopped by writing 0 in the bit associated with that module in the IVA.VIDEOSYSC\_CLKCTL register. The clock can be stopped, depending on whether the module is active when it is asked to be stopped. Reading the bit associated with the module in the IVA.VIDEOSYSC\_CLKST register lets the user check whether the module clock has effectively been stopped.

Writing 1 in the bit associated with that module immediately restarts clocks if they are stopped, and makes the module operational

When stopping the module root clock, take the following precautions:

- Synchronize with other CPUs/DMA's to determine whether another part of the system requires access to the module.
- Check whether the module has dependencies with other modules.
- Poll the status register in the module to determine whether the module is active.

**CAUTION**

Invalid configuration of [VIDEOSYSC\\_CLKCTL](#) causes unpredictable results.

For further system dynamic power savings, the sequencer CPU root clock can be independently divided when sequencer activity is reduced.

The root clock of the sequencer CPU can be divided by writing a value different from the value of the NOCLKDIV bit in the [VIDEOSYSC\\_CLKDIV](#) register. There is no software precaution to divide the sequencer CPU clock internally, in terms of traffic or idle conditions. However, this setting is static; that is, it is defined based on whether the sequencer MHz budget must run at full speed, based on a particular task or scenario. The [VIDEOSYSC\\_CLKDIV](#) value must not be changed twice within 16 sequencer clock cycles, or the second request can be ignored. This has no other side effect. Because of the requirement that the setting be static, it is acceptable to make this sequence uninterruptible, pad it with NOPs (or useful operations), or check for change effect, after changing the sequencer clock ratio.

The sequencer CPU clock can be independently divided by 2, 3, or 4, or not divided at all. By default, this clock is not divided.

## 14.4.10 Error Identification Process

Several mechanisms are available in the IVA2.2 subsystem to report errors at different levels.

### 14.4.10.1 Error Reporting for IDMA Module

The IDMA has its own error-reporting mechanism. The DSP megamodule implements an error register in EMC (IVA\_IDMA.IBUSERR) that latches errors for external invalid transactions on either the DMA (MDMA) bus or the configuration (CFG) bus. Errors are detected on the CFG and MDMA write status or read status interfaces. If an error is received and the corresponding command is an invalid transaction, the IVA\_IDMA.IBUSERR[31:29] ERR, IVA\_IDMA.IBUSERR[10:8] XID, and IVA\_IDMA.IBUSERR[2:0] STAT fields are updated accordingly. An error signaled through a non-0 read status is detected on the read data/status interface or a non-0 write status on the write status interface. Alternately, the EMC records an error if a read or write status response is detected for an unrecognized write ID.

---

**NOTE:** The user must ensure that the EMC detects/stores error information only for the first detected error on either the MDMA or CFG bus, regardless of whether it is a read or write status. In other words, a single error register (IVA\_IDMA.IBUSERR) is shared by read and write errors and by the MDMA bus and the CFG bus, and only the first error is stored. If a read error and a write error are detected at the same time, the write status error is given higher priority and is latched into the IVA\_IDMA.IBUSERR register.

---

When an error is detected and stored in the IVA\_IDMA.IBUSERR register, the EMC\_BUSERR event (EVT127, see [Table 14-3](#)) is available as a system event that can be selected as either a DSP CPU interrupt or an exception event.

The user can clear latched errors by writing 1 to the IVA\_IDMA.IBUSERRCLR[0] CLR bit.

### 14.4.10.2 Error Reporting for EDMA Module

The TPTC and TPCC blocks of the EDMA module also contain registers to inform the user of a problem during IVA2.2 external DMA communication.

#### TPCC Block

The TPCC provides a single error interrupt output CCERRINT (EVT38, see [Table 14-3](#)) that consolidates the error conditions:

- QDMA missed events (stored in the [TPCC\\_QEMR](#) register)
- DMA missed events (stored in the [TPCC\\_EMR](#) register)
- Transfer completion code error (stored in the [TPCC\\_CCERR\[16\]](#) TCCERR bit)
- Queue threshold error events (stored in the [TPCC\\_CCERR\[n\]](#) QTHRXCdn bit, n = {0,1})

When an error is detected, the CCERRINT event is asserted, because error events do not have enables.

---

**NOTE:** The CCERRINT event follows the same conventions as other TPCC interrupt outputs. When the error interrupt condition transitions from a no-errors-are-set state to at least one error set, the error output (CCERRINT) pulses high for one TPCC clock cycle. If additional errors are latched before the original error is cleared by the user, the TPCC does not generate additional interrupt pulses. The software must poll all bits during execution of the ISR, and clear all error conditions, so that subsequent error pulses can be generated by the TPCC block.

---

Error interrupts can be set and/or reevaluated by writes to the [TPCC\\_EEVAL](#) register.

### TPTC Block

The TPTC can also detect several error conditions:

- Read status or write status errors in the [TPTCj\\_ERRSTAT\[0\]](#) BUSERR status bit
- TR error in the [TPTCj\\_ERRSTAT\[2\]](#) TRERR status bit
- MMR address error in the [TPTCj\\_ERRSTAT\[3\]](#) MMRAERR status bit

Errors are recorded in the [TPTCj\\_ERRSTAT](#) register, regardless of whether they are enabled. They can be cleared from the [TPTCj\\_ERRSTAT](#) register only by writing 1 to the corresponding bit of the [IVA\\_TPTCj\\_ERRCLR](#) register.

The error details register ([IVA\\_TPTCj\\_ERRDET](#)) contains additional information about the first read status error or write status error detected. Future errors are bit-recorded until the [TPTCj\\_ERRDET](#) register is cleared.

If read status and write status are returned to the TPTC in the same cycle, the read or write status value that has an error (nonzero) is latched in the [TPTCj\\_ERRDET](#) register and the [TPTCj\\_ERRSTAT\[0\]](#) BUSERR bit is set. If both read and write status are nonzero, the write status is given priority for setting the [TPTCj\\_ERRDET](#) register. The [TPTCj\\_ERRDET](#) register is cleared by writing 1 to the [TPTCj\\_ERRCLR\[0\]](#) BUSERR bit.

If an error is enabled (by the [TPTCj\\_ERREN](#) register bits), the first occurrence of an enabled error generates a pulsed interrupt to the CPU by the TCERRINT event output (TCERRINT0 with EVT39 for TPTG0 and TCERRINT1 with EVT40 for TPTG1, respectively; see [Table 14-3](#)). Subsequent errors do not generate a new pulse until all accumulated errors are cleared by the CPU. The CPU clears bits in the [TPTCj\\_INTSTAT](#) register by writing 1 to the corresponding bit(s) of the [TPTCj\\_NTCLR](#) register.

#### 14.4.10.3 Error Reporting for the L3 Interconnect

L3 interconnect out-of-band errors are also reported by the external L3 interrupt signal ([I3\\_ia\\_iva2\\_initSError\\_o](#)). This signal corresponds to the EVT84 event and is directly connected to the [IVA2.2\\_nIRQ\[39\]](#) DSP CPU interrupt line. For more information about L3 interconnect error reporting, see [Chapter 5, Interconnect](#).

#### 14.4.11 Recommendations for Static Settings

The following static settings are recommended:

- `SYSC.SYSC_LICFG0.DMATRUECOMPEN = 1;` // DMA last write is nonposted.
- `SYSC.SYSC_LICFG0.GEMTRUECOMPEN = 1;` // DSP last write is nonposted.
- `SYSC.SYSC_LICFG0.GEMBURSTOPTEN = 1;` // DSP burst optimization

Ensure that the following setting is carefully set:

- All 2D DMA transfers source and/or destination are to a VRFB view (tiling structure):
  - // DMA 2D burst optimization
  - `SYSC.SYSC_LICFG0.DMA2DOPTEN = 1`

---

**NOTE:** If the preceding condition is not set accurately, setting the DMA2DOPTEN optimization can degrade performance.

---

**NOTE:**

1. A supersection type MMU page (16MB) must be defined for that VRFB view.
2. When the SYSC.SYSC\_LICFG0.PAGEXINGEN is set to 1, a 2D DMA should not cross a MMU page boundary. When this bit is set, it disables the hardware check mechanism for better performance (but the user should ensure that 2D DMA does not cross MMU pages).

Therefore, ensure that the following setting is carefully set:  
SYSC.SYSC\_LICFG0.PAGEXINGEN = 1.

**NOTE:** If the preceding condition is not set accurately, setting the PAGEXINGEN optimization can cause undefined results, including deadlock situations.

## 14.5 IVA2.2 Subsystem Register Manual

Table 14-98 lists the IVA2.2 memory space mapping as seen by the IVA2.2 DSP megamodule.

**Table 14-98. Instance Summary**

Module Name	Base Address	Size
IC	0x0180 0000	64K bytes
SYS	0x0181 0000	64K bytes
IDMA	0x0182 0000	64K bytes
XMC	0x0184 0000	64K bytes
TPCC	0x01C0 0000	64K bytes
TPTC0	0x01C1 0000	1K byte
TPTC1	0x01C1 0400	1K byte
SYSC	0x01C2 0000	4K bytes
WUGEN	0x01C2 1000	4K bytes
SEQ <sup>(1)</sup>	0x0009 0000	2K bytes
VIDEOSYSC <sup>(1)</sup>	0x0009 C000	4K bytes
iME <sup>(1)</sup>	0x000A 0000	4K bytes
iLF <sup>(1)</sup>	0x000A 1000	4K bytes
IA_GEM	0x000F 8800	1K bytes
IA_EDMA	0x000F 8C00	1K bytes
IA_SEQ	0x000F 9000	1K bytes

<sup>(1)</sup> These modules are accessible through DSP EFI port, with EFI instruction only. See Section 14.3.8, Video Accelerator/Sequencer Local Interconnect.

For more information on the IVA2.2 memory mapping, see Chapter 2, Memory Mapping.

**NOTE:** The MMU2 (IVA2.2 MMU) registers are described in Chapter 8, Memory Management Units. (The MMU base address is 0x5D00 0000 on the L3 interconnect.)

### CAUTION

The IVA2.2 registers are limited to 32-bit data accesses. 16-bit and 8-bit are not allowed and can corrupt register content.

### 14.5.1 IC Registers

This section provides information about the IC Module. Each register in the module is described in Table 14-100 through Table 14-122.

### 14.5.1.1 IC Register Mapping Summary

## 14.5.2 SYS Registers

This section provides information about the SYS Module. Each register in the module is described separately below.

### 14.5.2.1 SYS Register Mapping Summary

**Table 14-124. SYS Register Summary**

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address
PDCCMD	RW	32	0x0000 0000	0x0181 0000
REVID	R	32	0x0000 2000	0x0181 2000

### 14.5.2.2 SYS Register Descriptions

**Table 14-125. PDCCMD**

<b>Address Offset</b>	0x0000 0000	<b>Instance</b>	IVA2.2 GEMSYS
<b>Physical address</b>	0x0181 0000		
<b>Description</b>	Power-Down Command Register		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																GEMPD	EMCMEM	EMCLOG	UMCMEM	UMCLOG	DMCMEM	DMCLOG	PMCMEM	PMCLOG							

Bits	Field Name	Description	Type	Reset
31:17	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x0000
16	GEMPD	Power-down during IDLE: GEMPD = 0: Normal operation. Do not power-down CPU or DSP megamodule when CPU is IDLE. GEMPD = 1: Sleep mode. Power-down CPU and DSP megamodule when CPU enters IDLE state	RW	0
15:14	EMCMEM	SRAM Sleep Modes Determines the RAM sleep modes used by the EMC for powering-down internal memories.  0x0: No sleep mode supported 0x1: Sleep mode 1 Write 0x2: Sleep mode 2 - equivalent to sleep mode 1 Write 0x3: Sleep mode 3 - equivalent to sleep mode 1	RW	0x1
13:12	EMCLOG	Logic Clock Gating Modes. Determines to what degree the EMC gates its clock internally.  0x0: No clock gating supported beyond leaf clock gating. 0x1: Static clock gating of unused modules/regions when DSP megamodule is active (pmc_pd_pdstat[1:0] = 00) and Static clock gating when DSP megamodule is in standby (pmc_pd_pdstat[1:0] = 11)	RW	0x1
11:10	UMCMEM	SRAM Sleep Modes Determines the RAM sleep modes used by the UMC for powering-down L2 pages.  0x0: No sleep mode supported 0x1: Sleep mode 1 Write 0x2: Sleep mode 2 - equivalent to sleep mode 1	RW	0x1

Bits	Field Name	Description	Type	Reset
		Write 0x3: Sleep mode 3 - equivalent to sleep mode 1		
9:8	UMCLOG	Logic Clock Gating Modes. Determines to what degree the UMC gates its clockinternally.  0x0: No clock gating supported beyond leaf clock gating. 0x1: Static clock gating of unused modulesregions when DSP megamodule is active(pmc_pd_pdstat[1:0] = 00) and Static clock gating when DSP megamodule is in standby (pmc_pd_pdstat[1:0] = 11)	RW	0x1
7:6	DMCMEM	SRAM Sleep Modes Determines the RAM sleep modes used by the DMC for powering-down L1D pages.  0x0: No sleep mode supported 0x1: Sleep mode 1 Write 0x2: Sleep mode 2 - equivalent to sleep mode 1 Write 0x3: Sleep mode 3 - equivalent to sleep mode 1	RW	0x1
5:4	DMCLOG	Logic Clock Gating Modes. Determines to what degree the DMC gates its clockinternally.  0x0: No clock gating supported beyond leaf clock gating. 0x1: Static clock gating of unused modulesregions when DSP megamodule is active (pmc_pd_pdstat[1:0] = 00) and Static clock gating when DSP megamodule is in standby (pmc_pd_pdstat[1:0] = 11)	RW	0x1
3:2	PMCMEM	SRAM Sleep Modes Determines the RAM sleep modes used by the PMC for powering-down L1P pages.  0x0: No sleep mode supported 0x1: Sleep mode 1 Write 0x2: Sleep mode 2 - equivalent to sleep mode 1 Write 0x3: Sleep mode 3 - equivalent to sleep mode 1	RW	0x1
1:0	PMCLOG	Logic Clock Gating Modes. Determines to what degree the PMC gates its clockinternally.  0x0: No clock gating supported beyond leaf clock gating. 0x1: Static clock gating of unused modulesregions when DSP megamodule is active (pmc_pd_pdstat[1:0] = 00) and Static clock gating when DSP megamodule is in standby (pmc_pd_pdstat[1:0] = 11)	RW	0x1

PRI		INT	Reserved													FILL	COUNT										Reserved				

Bits	Field Name	Description	Type	Reset
31:29	PRI	Transfer priority. Used for arbitration between CPU and DMA accesses when there are conflicts. PRI = 111b: Low priority PRI = 000b: High priority	RW	0x0
28	INT	CPU interrupt enable INT = 1: Interrupt CPU (IDMA_INT1) on completion INT = 0: Do not interrupt CPU on completion	RW	0
27:17	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x000
16	FILL	Block fill: FILL = 1: Perform a block fill using the Source address field as the fill value to the memory buffer pointed to by the Destination address field. FILL = 0: Block transfer from the source address to the destination address.	RW	0
15:2	COUNT	16-bit byte count. Must be a multiple of 4 bytes. A transfer count of zero will not transfer any data, but will generate an interrupt if requested in the INT field.	RW	0x0000
1:0	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x0

## 14.5.4 XMC Registers

This section provides information about the XMC module, which contains the registers related to the three memory controllers of DSP megamodule: UMC, PMC, and DMC. Each register in the module is described separately below.

### 14.5.4.1 XMC Register Mapping Summary

**Table 14-166. XMC Register Summary**

19:16	MMID	Megamodule ID (always 0x0 for IVA2)	R	0x0
15:11	Reserved	Write 0s for future compatibility. Read returns 0.	W	0x00
10	NOINIT	No init upon cache config: when written '1', cache config is restored without re-initializing cache context (tags, validity bits) (this is assumed here that the restored cache settings are the same as prior to the execution of the IDLE instruction) when written '0', cache context is re-initialized (cache content is indirectly lost) this bit is always read as 0	W	0
9	IP	Global L1P invalidate (for backward compatibility, deprecated)	W	0
8	ID	Global L1D invalidate (for backward compatibility, deprecated)	W	0
7:5	Reserved	Write 0s for future compatibility. Read returns 0.	W	0x0
4:3	L2CC	L2 cache control	RW	0x0
		0x0: L2 cache operates normally		

Bits	Field Name	Description	Type	Reset
		0x1: L2 Cache is frozen		
		0x2: L2 cache is bypassed		
2:0	L2MODE	L2 Configuration Register	RW	0x0
		0x0: 0KB of L2 Cache		
		0x1: 32KB of L2 Cache		
		0x2: 64KB of L2 Cache

### 14.5.5 TPCC Registers

This section provides information about the TPCC module. Each register in the module is described separately below.

#### 14.5.5.1 TPCC Register Mapping Summary

**Table 14-261. TPCC Register Summary**

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address
TPCC_PID	R	32	0x0000	0x01C0 0000
TPCC_CCCFG	R	32	0x0004	0x01C0 0004
TPCC_DCHMAP <sub>i</sub> <sup>(1)</sup>	RW	32	0x0100 + (0x4*i)	0x01C0 0100 + (0x4*i)
TPCC_QCHMAP <sub>j</sub> <sup>(2)</sup>	RW	32	0x0200 + (0x4*j)	0x01C0 0200 + (0x4*j)
TPCC_DMAQNUM0	RW	32	0x0240	0x01C0 0240

### 14.5.5.2 TPCC Register Descriptions

**Table 14-262. TPCC\_PID**

<b>Address Offset</b>	0x0000	<b>Instance</b>	IVA2.2 TPCC
<b>Physical address</b>	0x01C0 0000		
<b>Description</b>	Peripheral ID Register		
<b>Type</b>	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SCHEME		Reserved		FUNC												RTL		MAJOR		CUSTOM		MINOR									

Bits	Field Name	Description	Type	Reset
31:30	SCHEME	PID Scheme: Used to distinguish between old ID scheme and current. Spare bit to encode future schemes EDMA uses new scheme, indicated with value of 0x1.	R	0x1
29:28	Reserved	Read returns 0.	R	0x0
27:16	FUNC	Function indicates a software compatible module family.	R	0x001

Bits	Field Name	Description	Type	Reset
15:11	RTL	RTL Version	R	0x--
10:8	MAJOR	Major Revision	R	0x3
7:6	CUSTOM	Custom revision field: Not used on this version of EDMA.	R	0x0
5:0	MINOR	Minor Revision	R	0x--

<b>Address Offset</b>	0x0004	<b>Instance</b>	IVA2.2 TPCC
<b>Physical address</b>	0x01C0 0004		
<b>Description</b>	CC Configuration Register		
<b>Type</b>	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						MPEXIST	CHMAPEXIST	Reserved	NUMREGN	Reserved	NUMTC	Reserved	NUMPAENTRY	Reserved	NUMINTCH	Reserved	NUMQDMACH	Reserved	NUMDMACH												

Bits	Field Name	Description	Type	Reset
31:26	Reserved	Read returns 0.	R	0x00
25	MPEXIST	Memory Protection Existence MPEXIST = 0: No memory protection. MPEXIST = 1: Memory Protection logic included.	R	1
24	CHMAPEXIST	Channel Mapping Existence CHMAPEXIST = 0: No Channel mapping. CHMAPEXIST = 1: Channel mapping logic included.	R	1
23:22	Reserved	Read returns 0.	R	0x0
21:20	NUMREGN	Number of MP and Shadow regions Read 0x0: 0 Regions Read 0x1: 2 Regions Read 0x2: 4 Regions Read 0x3: 8 Regions	R	0x3
19	Reserved	Read returns 0.	R	0
18:16	NUMTC	Number of Queues/Number of TCs Read 0x0: 1 TC/Event Queue Read 0x1: 2 TC/Event Queue Read 0x2: 3 TC/Event Queue Read 0x3: 4 TC/Event Queue Read 0x4: 5 TC/Event Queue Read 0x5: 6 TC/Event Queue Read 0x6: 7 TC/Event Queue Read 0x7: 8 TC/Event Queue	R	0x1
15	Reserved	Read returns 0.	R	0
14:12	NUMPAENTRY	Number of PaRAM entries Read 0x0: 16 entries Read 0x1: 32 entries (unsupported setting) Read 0x2: 64 entries	R	0x3

Bits	Field Name	Description	Type	Reset
		Read 0x3: 128 entries		
		Read 0x4: 256 entries		
		Read 0x5: 512 entries		
11	Reserved	Read returns 0.	R	0
10:8	NUMINTCH	Number of Interrupt Channels	R	0x4
		Read 0x1: 8 Interrupt channels		
		Read 0x2: 16 Interrupt channels		
		Read 0x3: 32 Interrupt channels		
		Read 0x4: 64 Interrupt channels		
7	Reserved	Read returns 0.	R	0
6:4	NUMQDMACH	Number of QDMA Channels	R	0x2
		Read 0x0: No QDMA Channels		
		Read 0x1: 2 QDMA Channels		
		Read 0x2: 4 QDMA Channels		
		Read 0x3: 6 QDMA Channels		
		Read 0x4: 8 QDMA Channels		
3	Reserved	Read returns 0.	R	0
2:0	NUMDMACH	Number of DMA Channels	R	0x5
		Read 0x0: No DMA Channels		
		Read 0x1: 4 DMA Channels		
		Read 0x2: 8 DMA Channels		
		Read 0x3: 16 DMA Channels		
		Read 0x4: 32 DMA Channels		
		Read 0x5: 64 DMA Channels

24	THRXC	Threshold Exceeded: THRXC = 0: Threshold specified by QWMTHR(A B).Qn has not been exceeded. THRXC = 1: Threshold specified by QWMTHR(A B).Qn has been exceeded. QSTATn.THRXC is cleared by CCERRCLR.QTHRXCn	R	0
23:21	Reserved	Read returns 0.	R	0x0
20:16	WM	Watermark for Maximum Queue Usage: Watermark tracks the most entries that have been in QueueN since reset or since the last time that the watermark (WM) was cleared. QSTATn.WM is cleared through CCERR.WMCLRn bit. Legal values = 0x0 (empty) to 0x10 (full)	R	0x00
15:13	Reserved	Read returns 0.	R	0x0
12:8	NUMVAL	Number of Valid Entries in Queuei: Represents the total number of entries residing in the Queue Manager FIFO at a given instant. Always enabled. Legal values = 0x0 (empty) to 0x10 (full)	R	0x00
7:4	Reserved	Read returns 0.	R	0x0
3:0	STRTPTR	Start Pointer: Represents the offset to the head entry of Queuei, in units of *entries*. Always enabled. Legal values = 0x0 (0th entry) to 0xF (15th entry)	R	0x0

<b>Address Offset</b>	0x1000		
<b>Physical address</b>	0x01C0 1000	<b>Instance</b>	IVA2.2 TPCC
<b>Description</b>	<p>Event Register:                      If ER.En bit is set and the EER.En bit is also set, then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. ER.En bit is set when the input event #n transitions from inactive (low) to active (high), regardless of the state of EER.En bit. ER.En bit is cleared when the corresponding event is prioritized and serviced. If the ER.En bit is already set and a new inactive to active transition is detected on the input event #n input AND the corresponding bit in the EER register is set, then the corresponding bit in the Event Missed Register is set. Event N can be cleared through sw by writing 1 to the ECR pseudo-register.</p>

<b>Address Offset</b>	0x1018		
<b>Physical address</b>	0x01C0 1018	<b>Instance</b>	IVA2.2 TPCC
<b>Description</b>	Chained Event Register: If CER.En bit is set (regardless of state of EER.En), then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. CER.En bit is set when a chaining completion code is returned from one of the TPTCs through the completion interface, or is generated internally through Early Completion path. CER.En bit is cleared when the corresponding event is prioritized and serviced. If the CER.En bit is already set and the corresponding chaining completion code is returned from the TC, then the corresponding bit in the Event Missed Register is set. CER.En cannot be set or cleared through software.

<b>Address Offset</b>	0x1020	<b>Instance</b>	IVA2.2 TPCC
<b>Physical address</b>	0x01C0 1020		
<b>Description</b>	Event Enable Register: Enables DMA transfers for ER.En pending events. ER.En is set based on externally asserted events (through tpcc_eventN_pi). This register has no effect on Chained Event Register (CER) or Event Set Register (ESR). Note that if a bit is set in ER.En while EER.En is disabled, no action is taken. If EER.En is enabled at a later point (and ER.En has not been cleared through SW) then the event will be recognized as a valid TR Sync EER.En is not directly writeable. Events can be enabled through writes to EESR and can be disabled through writes to EECR register. EER.En = 0: ER.En is not enabled to trigger DMA transfers. EER.En = 1: ER.En is enabled to trigger DMA transfers.

<b>Address Offset</b>	0x103C		
<b>Physical address</b>	0x01C0 103C	<b>Instance</b>	IVA2.2 TPCC
<b>Description</b>	Secondary Event Register (High Part): The secondary event register is used along with the Event Register (ERH) to provide information on the state of an Event. En = 0: Event is not currently in the Event Queue. En = 1: Event is currently stored in Event Queue. Event arbiter will not prioritize additional events.

**Table 14-389. TPCC\_QER**

<b>Address Offset</b>	0x1080		
<b>Physical address</b>	0x01C0 1080	<b>Instance</b>	IVA2.2 TPCC
<b>Description</b>	QDMA Event Register: If QER.En bit is set, then the corresponding QDMA channel is prioritized vs. other qdma events for submission to the TC. QER.En bit is set when a vbus write byte matches the address defined in the QCHMAPn register. QER.En bit is cleared when the corresponding event is prioritized and serviced. QER.En is also cleared when user writes a 1 to the QSECR.En bit. If the QER.En bit is already set and a new QDMA event is detected due to user write to QDMA trigger location and QEER register is set, then the corresponding bit in the QDMA Event Missed Register is set.

<b>Address Offset</b>	0x1094		
<b>Physical address</b>	0x01C0 1094	<b>Instance</b>	IVA2.2 TPCC
<b>Description</b>	QDMA Secondary Event Clear Register: The secondary event clear register is used to clear the status of the QSER and QER register (note that this is slightly different than the SER operation, which does not clear the ER.En register). CPU write of 1 to the QSECR.En bit clears the QSER.En and QER.En register fields. CPU write of 0 has no effect.		
<b>Type</b>	W		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

<b>Address Offset</b>	0x2000 + (0x200*n) n = 0 to 7		
<b>Physical address</b>	0x01C0 2000 + (0x200*n) n = 0 to 7	<b>Instance</b>	IVA2.2 TPCC
<b>Description</b>	Event Register: If ER.En bit is set and the EER.En bit is also set, then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. ER.En bit is set when the input event #n transitions from inactive (low) to active (high), regardless of the state of EER.En bit. ER.En bit is cleared when the corresponding event is prioritized and serviced. If the ER.En bit is already set and a new inactive to active transition is detected on the input event #n input AND the corresponding bit in the EER register is set, then the corresponding bit in the Event Missed Register is set. Event N can be cleared through sw by writing 1 to the ECR pseudo-register.

<b>Address Offset</b>	0x2020 + (0x200*n) n = 0 to 7		
<b>Physical address</b>	0x01C0 2020 + (0x200*n) n = 0 to 7	<b>Instance</b>	IVA2.2 TPCC
<b>Description</b>	Event Enable Register: Enables DMA transfers for ER.En pending events. ER.En is set based on externally asserted events (through tpcc_eventN_pi). This register has no effect on Chained Event Register (CER) or Event Set Register (ESR). Note that if a bit is set in ER.En while EER.En is disabled, no action is taken. If EER.En is enabled at a later point (and ER.En has not been cleared through SW) then the event will be recognized as a valid TR Sync EER.En is not directly writeable. Events can be enabled through writes to EESR and can be disabled through writes to EECR register. EER.En = 0: ER.En is not enabled to trigger DMA transfers. EER.En = 1: ER.En is enabled to trigger DMA transfers.
